THE Newton

LONG WORKING DISTANCE ATTACHMENT

. . . provides a working distance of 12.8 mm. between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm. objective.

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

For Ultra-violet absorption research

Vitreosil Spectrophotometer Cells are made from specially selected transparent fused quartz, which has a high efficiency in the Ultra-violet range. The Cells have fused joints and are available in a standard range of sizes suitable for most spectrophotometer equipment. The standard sizes of Vitreosil Cells can be supplied matched if required.

Taking the 'Frowns' from HIGH VACUUM PLUMBING

Nothing can be simpler than screwing down a metal ring by hand, and that is how easy becomes the complicated business of 'plumbing' high vacuum systems when 'SPEEDIVAC' vacuum unions are specified. Simple design and precision vacuum engineering eliminate long-standing problems—just a few turns of the wrist and you have a permanent, rigid, leak-proof connection—and it's just as simple to take down when necessary.

Sizes from 1/16 in. to 2 in. diam.

DEW POINT APPARATUS
IMPROVED MODEL

This instrument will interest any person or organization concerned in the measurement of the dew point or relative humidity of air in large or confined spaces.

The re-design permits a more rapid appearance and disappearance of the dew formation, while an insulated thermometer of greater length enables more accurate temperature readings to be taken.

NOW

ALSO AVAILABLE IN
SPECIAL QUALITY RANGE

The high performance of Mullard stabilisers has been improved even further by the introduction of *Special Quality* types, which will operate satisfactorily under rigorous conditions of shock and vibration. These special versions of normal production types combine extra-rugged construction with what has proved to be an inherently reliable principle of design, and they will be available in addition to the normal range.
Samples selected from every production batch of *Special Quality* tubes are tested against Services' specifications to withstand impacts of 500g and vibration of 6g at 175 c/s.
All three of the *Special Quality* tubes can be supplied with either pin or flying lead bases. Your enquiries for further details of these and other stabilisers in the Mullard range are welcomed at the address below.

Special Quality Type No.		Electrical Equivalent		Burning Voltage (V)	Current Range (mA)	Maximum Ignition Voltage (V)
Pin Base	Flying lead Base	Mullard	British Services			
M8098	M8142	85A2	CV449	85	1 to 10	115
M8206	M8207	90C1	—	90	1 to 40	115

The absorption spectrum of a substance has, with good reason, been called its most revealing characteristic. A plot of absorption against wavelength can give complete analytical data accurately, rapidly, and with the minimum of effort. Hence the increasing reliance of the chemist on the spectrophotometer for research, routine analysis and control of product quality. A full account of the range and applications of these leading instruments will be supplied by Unicam Instruments of Cambridge on request.

PRECISION BS INSTRUMENTS

Refractometers for Industry and Research

Our well-known standard Abbe type refractometer has a refractive index scale on glass and is read by transmitted light, thus leading to greater convenience in taking measurements and a higher degree of accuracy.

The instrument as illustrated is supplied with degree scale arc and micrometer screw reading directly to 10 seconds, corresponding to a refractive index accuracy within 0.00005. Conversion tables for use with sodium light are supplied.

DELIVERY FROM STOCK

Full particulars sent on application.

We shall be pleased to demonstrate these instruments and give any advice within our power, if you will call at our Works.

ATOMIC ENERGY FOR PEACEFUL PURPOSES

LITTLE more than a year ago, on December 8, 1953, President Eisenhower first made his proposals for an international pool of atomic materials for peaceful purposes, and on September 25 the governments of the United States and of the Soviet Union disclosed the details of these proposals and of the unsuccessful efforts of the two countries to reach agreement on that plan. Progress has since been more marked than might have been expected, even although the published notes and memoranda exchanged between the two countries indicated the willingness of both countries to continue the negotiations. Agreement had then already been reached between the United States and six other nations to establish an international agency which would foster the growth and spread of the new atomic technology for peaceful purposes. Atomic materials were to be set aside for projects sponsored by the agency, and in due course the United States was to establish a reactor school to train representatives of friendly nations in the skills needed for their own atomic purposes.

At the end of September last, the United States delegate to the United Nations asked the steering committee to place on the agenda of the General Assembly as an important and urgent matter the United States proposals for the establishment of an international atomic energy agency for peaceful purposes. The Soviet Deputy Foreign Minister then suddenly announced his government's readiness to discuss the question in the General Assembly, though the discussions of the following two months have made it no clearer whether the U.S.S.R. is willing to participate in or support the international agency. Both Great Britain and the United States have given further weight to their proposals for promoting internationally the constructive use of atomic energy by their announcements that they are holding definite amounts of fissionable material for use in atomic research reactors abroad, and by their offer on November 5 to train foreign scientists as a first practical instalment of the Eisenhower plan for an 'atomic pool'. In this connexion Sir Pierson Dixon, the British delegate to the United Nations, stated specifically to the Political Committee of the Assembly that the British government could immediately offer a number of places in its four-week training course in the radioactive isotope school at the Atomic Energy Research Establishment at Harwell, and that other places might be made available at the Harwell School of Reactor Technology with courses lasting for periods of months.

It should be appreciated that, as Sir Winston Churchill told the House of Commons on November 16, Great Britain is at present the greatest exporter of radioactive isotopes in the world. Sir Pierson Dixon also told the Political Committee that it is Britain's intention to use the proposed agency to share our knowledge with other countries to the maximum extent permitted by security considerations and the demands for man-power and materials of our own projects. Moreover, the relaxation of restrictions on the exchange of information on atomic energy made possible by the Atomic Energy Act of 1954, both facilitates co-operation in the development of nuclear energy between the United States and other countries and further attests the sincerity of the American proposals to an extent which it is difficult for those outside the United States fully to appreciate.

In the course of the discussions at New York, the original American proposals were considerably modified. The draft resolution which the eight Western Powers specially interested in atomic energy sent to the Political Committee early in November noted the progress made in the negotiations between the eight Powers themselves—Great Britain, the United States, France, Canada, Australia, South Africa, Belgium and Portugal—for the establishment of an international agency, and recommended that they should continue. The resolution gave no lead, however, as to the functions, powers, organization, location, management, methods of voting or membership of the new body, and there was evidently no agreement among the sponsors themselves. Indeed, the United States Administration seems now to prefer bilateral arrangements with countries of its own choice for channelling technical knowledge and materials to the multilateral pool proposed by President Eisenhower. The international agency is thus left with functions little more than the preparation of bibliographies, the identification of scientific needs and resources, and the promotion of training facilities. In particular, this revised plan fails either to stimulate co-operation between East and West or to promote the use of nuclear experience and materials in the under-developed territories.

The resolution which was finally adopted unanimously by the Political Committee of the General Assembly on November 23, while not going into detail, referred specifically to the original objectives. It endorsed the negotiations now in progress, and expressed the hope that the international atomic agency will be established without delay, and that when the agency is established it will negotiate an appropriate form of agreement with the United Nations. The resolution recalls specifically, however, the initiative taken by the President of the United States on December 8, 1953, and international co-operation is recognized as important and urgent "in developing and expanding the peaceful uses of atomic energy to assist in lifting the burdens of hunger, poverty and disease". Moreover, the proposed international agency is "to facilitate the use by the entire world of atomic energy for peaceful purposes and to encourage international co-operation in the further development and practical application of atomic energy for the benefit of mankind".

The resolution also calls for an international technical conference of governments to be held under the auspices of the United Nations not later than August

1955, "to explore means of developing the peaceful uses of atomic energy through international co-operation and, in particular, to study the development of atomic power and to consider other technical areas such as biology, medicine, radiation protection and fundamental science—in which international co-operation might most effectively be accomplished". All members of the United Nations and the specialized agencies are to be invited to the proposed conference, and an advisory committee comprising representatives of Brazil, Canada, France, India, the Soviet Union, Great Britain and the United States was to be established to issue invitations to it, to prepare and circulate a detailed agenda, and to provide the staff and services required.

In organizing this conference, the Secretary-General of the United Nations, M. Hammarskjold, has already engaged as his special consultant Dr. Gunnar Randers, head of the Kjeller Institute of Atomic Research in Norway and director of the joint Dutch–Norwegian atomic research project. The conference, which is expected to meet towards the end of August in Geneva, is likely to be a serious scientific congress, and its purpose will be not the exchange of views so much as to tackle the practical technical and economic problems involved, for example, in the generation of power from nuclear energy in various parts of the world, and particularly in under-developed areas. The advisory committee named in the Assembly's resolution is expected to meet this month.

All this represents a highly satisfactory outcome of the United Nations debate on atomic energy. The main Russian objections have been either met or withdrawn, and whether or not the U.S.S.R. participates, it has been well worth while that Britain and the United States should demonstrate their intention of going forward in collaboration with any nations willing to do so. It has shown the whole world that the major Western governments are prepared to lift some of their secrecy restrictions, and to take the initiative in helping others; and in particular it shows the industrially less advanced nations that they will not be denied the benefits of nuclear energy, however acute may be the limitations of their industrial and financial resources.

If, however, nuclear energy has thus been placed fairly in the context of industrial development and human welfare, in contrast to that of warfare and destruction, it is important that excessive expectations as to the rate of progress should not be aroused. When the international agency is ready to act as a clearing-house for information and assistance, its major task will be to ensure a clear public understanding of the limitations as well as the possibilities of nuclear power and the production and applications of fission products, including radiochemicals. Even in the United States, there is little chance of any important nuclear power production for another ten years, and it will then be a complementary source of energy rather than supplementing coal and oil in meeting the demand for electric power. Its principal effect in the United States is likely to be to prevent power costs rising because of higher fuel costs. In Great Britain it is hoped to have a nuclear reactor producing electricity commercially by 1958. It must therefore be made clear at the outset that, even for nations with the most advanced technical developments in this field, substantial contributions to industrial power from this source are unlikely within the next decade. Undue optimism in Africa or Asia, for example, might engender disappointment or suspicions which would hinder co-operation. This is one point at which scientists, both individually and collectively, through such bodies as the Atomic Scientists Association, and particularly the Science Co-operation Centres of the United Nations Educational, Scientific and Cultural Organization, may be able to assist. By turning discussion from questions such as the morality of atomic warfare to the constructive consideration and public understanding of the practical conditions for co-operation in the development of nuclear energy for peaceful purposes, or the application of fission products in medicine, agriculture and elsewhere, not only will the possibility of misunderstanding or frustration be minimized, but also the conditions promoted in which international agreement in relation to disarmament generally might be reached.

There is a further reason why the proposals for co-operation in the development of nuclear energy for peaceful purposes concern scientists in general. Any step which reduces the area of secrecy in regard to scientific and technical knowledge will be welcomed in principle by scientific men. The present proposal promises also to affect the costs of energy and the availability of raw materials as well as of fissionable material in various countries. The whole history of science shows that the exchange of scientific and technical knowledge is seldom in one direction for long. Britain may be at present the world's largest exporter of radiochemicals, but it is probable that before long she will be receiving from the European Agency for Nuclear Research at Geneva as well as contributing to it.

Before that stage can be reached, however, and especially in regard to the under-developed areas, there are certain conditions of scientific and technical development to be achieved; and it is important that these should be clearly understood. It is of little use, for example, for Britain to be able to supply radioisotopes to the hospitals of the Middle East, South-East Asia or Central Africa if the technicians are not on the spot to use such materials properly, or if the necessary equipment—which is expensive—is not available. Neither the technicians nor the equipment can be supplied without forethought. Staffs have to be found and trained, and if that training is given overseas, there is the question of cost.

Not all the territories which might benefit from such supplies and techniques can easily provide either the candidates for training or the finance to support and to equip suitably the institutions in which they will work when trained. Not all are yet ready to divert resources to such purposes, and still more does this apply to the production of nuclear power. The provision of the necessary technical knowledge and trained technicians in under-developed areas, where nuclear power could contribute to industrial development and the raising of standards of living, will by itself do nothing to solve the economic and financial problems involved in the construction of the reactors and other plant required Such problems will be encountered even if technical help is limited to those under-developed areas where nuclear energy promises to be the most economical source of power Besides technical aid in the narrower sense, and probably—at least at the start—some overseas technical experts, such countries need the political maturity which can create the conditions likely to attract such experts, and also the substantial capital required to finance the developments and to set in train a well-balanced and intelligently applied economic programme Much more is implied than a programme of scientific and technical co-operation, or of education in the scientific and technical sense

Moreover, if the administration in under-developed countries is to be given a chance to raise its standards, too great care cannot be taken to avoid minor causes of misunderstanding and prejudice Even in Great Britain, the Atomic Energy Authority has encountered difficulties, for example, in the disposal of wastes, through public ignorance and prejudice In more backward countries, the consequences of mistakes arising through moving too fast and in advance, for example, of an adequate supply of those competent to handle radiochemicals safely, might well prejudice fatally the efforts of a local administration to establish the favourable conditions for economic development

The British and the American governments have indeed given a welcome lead, and the direct and indirect possibilities of the proposals approved by the United Nations General Assembly cannot be over-stressed If they are to be realized, much patient constructive effort will be required, and not least by scientists themselves On them must rest no small share of responsibility for the success of the international scientific conference to be called next summer Beyond that they could do something to promote the educational work which is required to promote a full public understanding of what is involved in co-operation in the development of nuclear energy, and the price that is demanded in self-discipline even in its utilization for peaceful purposes

The repeated questions in the House of Commons as to the effect of atomic explosions on the weather testifies to the need for that educational work, even in the Western countries That influence has been consistently denied by meteorologists , nevertheless it forms the subject of a short communication to the Paris Academy of Sciences (November 15) by C -M Martin The danger of test explosions of nuclear weapons causing a permanent change in terrestrial radioactivity was admitted by Prof A Haddow in addressing the Parliamentary Association for World Government at a meeting in the House of Commons on December 8, and Prof Haddow made two useful suggestions First, he advocated an international meeting of scientists on an unofficial level, much on the lines which Prof Lewis Mumford suggested last year to the American Philosophical Society, to discuss the implications of atomic warfare , and second, the founding of a permanent body forming a link between the political world and the United Nations and the world of science The clear establishment of the facts and then making them widely known in some such way are at least safeguards against irrational prejudice suddenly forcing unilateral action which might endanger the public interest There can indeed be few fields where the co-operation of men of science is more essential in promoting the public understanding upon which wise policy and effective international co-operation must be based than in that of nuclear energy, its development, its application and its control

A CLASSICAL RESEARCH ON PLANT RESPIRATION

Analytic Studies in Plant Respiration

By the late F F Blackman Pp x+232 (Cambridge At the University Press, 1954) 40*s* net

UNDER the direction of the late F F Blackman some thirty-four years ago, the output of carbon dioxide by each of twenty-one Bramley's Seedling apples, in atmospheres of a variety of compositions, was followed over various periods of time These atmospheres included normal air, pure nitrogen, pure oxygen and mixtures of oxygen and nitrogen in which the concentration of the former was less than in normal air. A feature of all the experiments was a transference of the apple under investigation from one atmosphere to another of different composition The results of this research, in so far as it concerned apples which for part of the experimental period had been kept in an atmosphere of nitrogen, were afterwards published as three papers in the *Proceedings of the Royal Society* during 1928 It was in the third of these papers that Blackman, from his masterly analysis of the experimental data, put forward his theory of oxidative anabolism

Although the experimental data dealing with carbon dioxide output in environments possessing low oxygen concentrations were touched on in that paper, and although the records of all the experiments were brought together as an appendix to the second paper, a detailed analysis of the experimental data was never published by Blackman He had, nevertheless, spent much time and thought on the matter, and he had, indeed, prepared a series of papers in which the data were subjected to an analysis as exhaustive and masterly as that exhibited in the papers already published on carbon dioxide output in air and in nitrogen The present volume contains these papers, six in number, previously unpublished, together with a reprint of the three published in 1928 , it thus contains a complete account of the experiments of 1920–21 with Blackman's analysis of the data and the metabolic concepts he derived as a result of this

In reading these papers, one cannot fail to be impressed by the amount Blackman was able to derive from the experimental data It must be realized that, when the experimental work was undertaken, next to nothing was known of the effect of varying oxygen concentration on respiration , indeed, even now our knowledge of this is very limited From the data of carbon dioxide output alone, Blackman was able to separate the fermentation and respiration components of the total carbon dioxide output in low oxygen concentrations and to show convincingly that, as the fermentation component fell and the respiration component rose with increasing oxygen concentration, the carbon dioxide of respiration replacing that of fermentation bore a constant relation to the drop in fermentation up to the extinction point, that is, the lowest oxygen concentration in which fermentation fails entirely His analysis further led Blackman to the conclusion that oxygen plays a threefold part in respiration. In addition to its oxidation function resulting in the production of carbon dioxide, and its anabolic function in oxidative anabolism, Blackman came to the conclusion that oxygen serves as an activator of the rate of conversion of inactive carbohydrate to the activated carbon compound which forms the starting-point of fermentation, and from which the substance forming the starting-point of respiration, if not identical with it, is derived.

In assessing the value of Blackman's work on respiration, it is necessary to bear in mind two things One of these is the time at which the work was done The papers now published for the first time are dated from 1935 to 1937, when views now current on the fermentation and respiration mechanisms were still only in an early stage of their formulation The second point, and this is all-important, is that Blackman's approach to the problems of respiration was that of a physiologist and not that of the biochemist He wrote (p 127) " we stress that our objective is to generalize the metabolism into classes of reactions and the biological control of their rates. This we take to be the proper objective of physiology as segregated from biochemistry which seeks to individualize the reactants and the products of intermediate metabolism". The reader of these papers can be in no doubt that in them Blackman's objective was achieved

Thirty-four years is a long time in the history of modern plant physiology It may well be asked why so long a period has elapsed between the winning of the experimental data and the publication of the full conclusions derived from them The answer is no doubt to be found in Blackman's desire for perfection It seems likely that he was still not satisfied with some, at any rate, of the papers now published for the first time. There are few of us who would not have been satisfied with very much less Plant physiologists should be grateful that this record of work of the leading British plant physiologist of a century should have been made generally available

WALTER STILES

GENETICS AND THE CHROMOSOMES

Animal Cytology and Evolution

By M J D. White Second edition Pp xiv+454. (Cambridge At the University Press, 1954.) 45s. net

IN all sexually-reproducing plants and animals the reproductive cycle depends on an alternation of two changes in the nucleus an addition at fertilization, and a reduction at meiosis. Fertilization is simple, but meiosis is complicated It consists, however, in a chain of events which almost universally shows a certain causal sequence, thus (1) crossing-over is a condition of chiasma-formation, (2) chiasma-formation is a condition of metaphase pairing, (3) metaphase pairing is a condition of segregation and hence of reduction, (4) reduction is a condition of continuing sexual reproduction.

A most important object of the genetic study of chromosomes in recent years has naturally been to find out the meaning of these rules It has appeared, for example, that the exceptions are confined to one sex, the heterozygous sex, in certain groups of dioecious animals The rules always hold for the other sex Hence, crossing-over is (at least) co-extensive with sexual reproduction, which is therefore invariably a mechanism of gene recombination within a group of organisms Thus the cellular sequence of events crosses a population sequence of events and from this intersection arises a general chiasma theory, according to which a sexual species is a group of organisms enjoying gene recombination, while a chromosome is a group of genes capable of such recombination

In the past twenty-five years the uniformity of plants has confirmed these principles, while the diversity of animals has directed attention to their exceptions, exceptions which illustrate the physiological control and evolution of the chromosome mechanism itself For the development or limitation or re-interpretation of these ideas we naturally turn to an evolutionary account of the chromosomes in animals

The first edition of this book by Dr M J D White was handicapped by the difficulty of separating animals from plants The exceptions could not be related to the rules Nevertheless, both were described and the fundamentals were correct How does the second edition compare with it ? The great fundamental is, of course, crossing-over The treatment of this question may be taken as representative of Dr. White's methods and point of view

It was Janssens who in 1924 made the first important chromosome contribution to the theory and based it on the study of grasshopper chromosomes According to White (p 83), Janssens assumed that "each chiasma is a place where two out of the four chromatids . have undergone crossing over" This is the current theory of crossing-over But it was not Janssens's theory nor did White's first edition say so Janssens assumed that at any chiasma 0, 2 or 4 chromatids might have crossed over earlier , and two of them might cross over later

Janssens's theory was too complex and too permissive to be disproved Not so his observations. Certain of them remain unsurpassed and undisproved He described (*l c*, p 178) and illustrated "l'absence de stade pachytène" in the grasshopper *Mecostethus grossus* A restriction of pairing to one end of each chromosome led to a restriction of chiasma-formation and crossing-over to this end This highly significant observation has since been confirmed by observations in plants and animals which underlie the current theory of meiosis But White (p 98) claims the support of Janssens for an exactly opposite account of the species "there is direct observational evidence that pairing is complete at pachytene"

Assisted by this misreading of Janssens, White maintains a theory of the mechanism of crossing-over which he had advanced in his first edition. It is that "chiasma localisation is intimately connected with the alternation of heterochromatic and euchromatic segments" (p 98), or the distribution of euchromatin and heterochromatin is "largely responsible for determining the distribution of crossing over along the length of the chromosome" (p 373) A little while before White advanced this view it had, however, been disproved by studies on plants carried out in order to test such an obvious possibility For example, in *Fritillaria* there are species with and without heterochromatin but both groups include species with localization and without localization of chiasmata In *Paris* also there are species with and without heterochromatin but both kinds have localization of chiasmata In both genera all localization is near the centromere but in *Fritillaria* the heterochromatin is near the centromere, in *Paris* it is away from the centromere Nature apparently has in every circumstance misunderstood the theory

Dr White does not refer to the prior disproof of his views or to the relevant papers He merely wipes out the whole field of inquiry He points out that studies showing heterochromatin in plants by means of nucleic acid starvation are "suspect" and their description merely "picturesque terminology" On the other hand, studies showing the absence of heterochromatin in plants merely arise from "inadequate technique" and "insufficient evidence" The conclusions of those who have pursued this question are "untrue" (p 373), and the critical citation is removed from this edition

In general, Dr White has attempted to cut out and throw away the theories he accepted in his first edition But his treatment has been careless and the result is inconsistent The theory, an evolutionary theory, of pairing segments and differential segments in sex chromosomes was originally derived from the general chiasma theory At one stage Dr White accepts it (p 285) But elsewhere he dismisses the interpretation on which it rests in *Drosophila* as "impossible" (p 223) and in mammals as a "vue de l'esprit" (p 286) Dr. White's application of this theory (which he illustrated as Fig. 84 in his first edition) was, I agree, impossible. But that was because he had copied it incorrectly from the original author He has now cut it out

Again, Dr White rejects the view that parthenogenesis is an escape from sterility "there is no reason to believe that it applies to animals at all" (p 340) But three pages later he adopts the rejected view parthenogenesis avoids the results of unsuccessful meiosis, "we consequently find that a number of species and races of parthenogenetic animals are polyploid " (p 343)

Dr White too often omits to cite the publications he is contradicting and too often also he seems to have forgotten the evidence he is contradicting even when it appeared in his first edition For example, when he asserts that the centromere can be broken and is not therefore "a special kind of gene" (p 26), one supposes that he has forgotten that the theory of the centromere as a group of genes was derived from observations of its breakage When he says that in a bivalent with a single chiasma "obviously the terms *reductional* and *equational*, as applied to the two meiotic divisions have lost all genetic meaning" (p 232) one supposes that he has forgotten that this principle provides us with the means of mapping the chromosomes of the lower organisms. But when he states (p 381) that "structural rearrangements" in chromosomes are of no importance in the origin of species and the hypothesis "is now seldom mentioned", can one suppose that he has forgotten all the evidence, old and new alike ?

Above all, as Dr White nearly stumbles on the principle of the evolution of genetic systems, one wonders whether he has noticed the idea that all chromosome behaviour is subject to physiological control which, being also genotypic, is subject to selection and adaptation But, alas ! These words are not in Dr White's index The problems behind them raise no difficulties for him Their solution has made no impression on him He writes, therefore, not of evolution as we now understand it, but of comparative anatomy The difficulties with which we find him struggling are merely due to his being out of his depth when he writes about chromosomes and evolution

C D DARLINGTON

CHEMICAL MICROSCOPY

Microscopy for Chemists

By Prof Harold F. Schaeffer Pp viii+264 (New York D Van Nostrand Company, Inc , London Macmillan and Co , Ltd , 1953) 34*s* net

ANY attempt to overcome the reluctance of the average chemist to take advantage of the many useful applications of the optical microscope in chemical practice deserves encouragement, and for that reason this introduction to chemical microscopy is to be welcomed. The author has dealt with most of the important aspects of the subject in a clear and concise manner, and while pointing out that it is best studied under the personal guidance of a competent instructor, he has endeavoured to present his material in such a way as to be intelligible to the worker who must depend on his own resources. Doubtless with the needs of such lone students especially in mind, he has given in the last ninety pages of the book a series of illustrative experiments with full explanatory notes and instructions It is good to see that a description of the Kofler hot stage is included, though it is a pity that a little more space could not have been found in which to deal more fully with some uses of this valuable accessory which only receive bare mention, such as, for example, the elegant contact method for studying phase relationships in binary systems

The least successful part of the book is the chapter dealing with polarized light Admittedly the author states that an adequate treatment of optical crystallography lies beyond the scope of the book, but some parts of this section are quite misleading Not only are there several errors of fact, but also the treatment fails to make clear that the optical properties of anisotropic crystals are directional in character, and that what is observed under the microscope depends on the particular optical section which a crystal presents and, in lesser degree, on its thickness It is true that there is some mention of optic axes near the end of the chapter, but by the time the reader reaches this point, the damage will have been done. Extinction behaviour is discussed without any reference to the morphological properties of crystals (except by implication), and parallel extinction is incorrectly given as a property possessed solely by uniaxial crystals. The diagram on p 111, which seems to be intended to show the changes in a typical biaxial interference figure on rotating the stage (though the type of figure is not specifically stated), is quite wrong It gives a uniaxial cross and ring as the appearance of the figure in the extinction position, while the isogyres are referred to as parabolas and are shown as moving in and out bodily, that is, not pivoting about the melatopes Again, in distinguishing between uniaxial and biaxial crystals, the statements are made that a uniaxial crystal has two refractive indices and a biaxial crystal three, without making clear that these are the principal refractive indices and that they are not (with the exception of ω) necessarily presented by a random section, and that certainly no biaxial section presents three indices as the beginner might infer

When dealing with that part of chemical microscopy which may perhaps be described as ordinary chemistry in miniature, the author is on firm ground, and the treatment is all that could be desired So too is that in the introductory chapters on the principles, construction and use of the compound microscope and its accessories The book is on the whole well produced, though consideration might be given in any future edition to improving the clarity of some of the photomicrographs of typical crystalline precipitates Except for those parts criticized above, the book is a useful addition to the literature of chemical microscopy, particularly for the beginner

NATIONAL MUSEUM OF VICTORIA

Collections of a Century

The History of the First Hundred Years of the National Museum of Victoria By R T M Pescott Pp xii+186+18 plates (Melbourne National Museum of Victoria, 1954) 30*s* (Australian)

It is proper that museums, in common with other traditional institutions, should pause at intervals and examine critically their past achievements, and from their failures or successes formulate their policies for the future in accordance with past experience The present volume is a painstaking compilation by the director, Mr R T M Pescott, of the history of the first hundred years of the National Museum of Victoria Dedicated to the memory of that great geologist, Frederick McCoy, the book forms a permanent record of the Museum It also contains such pertinent remarks and observations that it has much of value for the whole museum profession and indeed for all those interested in museums In an apt foreword, Sir Russell Grimwade, chairman of the trustees, stresses the especial responsibility of Australians to preserve a knowledge of the past in a country which, at any rate in its natural history aspects, has seen so many violent changes in the historical past

In common with many museums, the National Museum of Victoria owes its origin to a local philosophical society and individually to an English army officer, Captain Andrew Clarke R E, who had the vision of a comprehensive museum in the colony of Victoria Incidentally, it was he who gave it the right type of initial policy and insisted that its main function was to instruct rather than bewilder with a confused jumble of curiosities In 1854 McCoy accepted the position of professor of natural science in the University of Melbourne and in 1858 was appointed director of the Museum He remained in this position until his death in 1899 At the outset, he clearly differentiated between university museums, which exist for internal teaching purposes, and national museums, which contain material of national value for the instruction and recreation of the community By means of wise purchases and other acquisitions McCoy amassed material and the present comprehensive state of the natural history collections owes much to his foresight and vision For example, the original description of the gorilla did not appear in print until 1847, when a skull only was included, yet by 1863 McCoy actually had specimens of these animals on display in his Museum Of outstanding importance was the purchase in 1863 of the famous John Curtis collection of insects with many types, both British and foreign, offered, strangely enough, by Dr J E Gray, of the British Museum

In 1870 eighteen trustees were appointed to control the Museum, and McCoy had a particularly difficult time in obtaining funds He complained of frustration in the execution of his plans, and it is to his credit and indomitable courage that he carried on with the Museum and eventually completed forty-three years of service, collecting some 510,000 specimens valued at more than £40,000.

After the death of McCoy, the Government of the State of Victoria turned naturally for advice on the future policy of the Museum to Prof (later Sir) Baldwin Spencer, who had been appointed to the chair of biology in the University of Melbourne in 1887 He was appointed honorary director, and the Museum was moved from the precincts of the University to the Public Library buildings The first result of the new policy was the inclusion of anthropology in addition to the sections of natural history, and secondly, the arrangement of the collections on an evolutionary rather than a geographical basis Spencer resigned in 1928 in order to write up his earlier, and conduct new, researches, but in 1929 he died of a sudden heart attack

James Kershaw, previously curator, was appointed director after the Museum had been served by two honorary directors (McCoy and Spencer) for a period of seventy-five years—surely a unique record. Kershaw brought to his new position a wealth of experience in the service of the institution Since 1925 the Museum had unfortunately experienced a decline in public interest, and one of Kershaw's first acts was to introduce dioramas and habitat groups—the first to be seen in Australia He also planned a special aboriginal art exhibition In 1931 Kershaw severed his official connexion with the Museum—closing a record of more than seventy years continuous service of father and son—and Mr D J Mahoney was appointed director Mahoney placed an emphasis on the function of research in museums and immediately set about the reorganization of the *Memoirs of the National Museum* He also advised the strengthening of the small staff by the appointment of honorary workers

It was in 1944 that the present director was appointed, and during the ten years he has been in office it is evident that he has devoted much attention to the educational aspects of the Museum He has already laid down how an educational objective could be achieved in a new building on a site which was reserved in 1948

This well-produced volume closes with a chronological history of the institution and a list of the present trustees and staff It is no dull monotonous historical record but a vivid—in some cases day-by-day—recital of the activities of a live institution Moreover, it contains much that will serve as an inspiration to Mr Pescott's museum colleagues throughout the world

F S Wallis

History of the Primates

An Introduction to the Study of Fossil Man By Prof W E Le Gros Clark Fourth edition. Pp. 6+119 (London British Museum (Natural History), 1954.) 4s

PROF W E LE GROS CLARK is indeed a master in his subject, and the fourth edition of his "History of the Primates", printed for the trustees of the British Museum (Natural History), contains the latest ideas on this problem put in a way that the non-specialist can appreciate Of recent years, much new evidence has accumulated The discovery in Kenya of primitive apes of Miocene age (very possibly the basal 'stuff' from which has evolved both the line of man and of the anthropoid apes) and the finding by Prof R A Dart and Dr R Broom in South Africa of the early Pleistocene Australopithecinae (ape-men not yet classed as human by the author, Prof Le Gros Clark, until evidence turns up to show that they were talkers and tool makers) have completely revolutionized previous ideas on the subject

The Piltdown hoax is treated firmly, if discreetly, and, of course, the Galley Hill skull is dismissed as being of a relatively recent date He also dismisses as unproved the great antiquity of the Kanam and Kanjera finds in Kenya The fact that new test methods have been discovered, which would make another such hoax as that of Piltdown impossible, is pointed out, these new methods, some chemical such as the fluorine test and others physical such as the carbon-14 method of dating, are extremely valuable aids for study quite apart from the question of detecting frauds

Prof Le Gros Clark concludes his book with a timely warning "If Man has gained his intellectual dominance over his fellow creatures by concentrating his evolutionary energies on the development of his brain, it remains to be seen whether he can now maintain his position by contriving a method of living in orderly relations with members of his own species If he fails to do so he may yet follow the example of many other groups of animals which have achieved a temporary ascendancy by an exaggerated development of some particular structural mechanism He may become extinct" M C BURKITT

Bernstein Polynomials

By Prof G G Lorentz (Mathematical Expositions, No 8) Pp x+130 (Toronto University of Toronto Press, London Oxford University Press, 1953.) 45s net

THIS book consists of four chapters In the first, properties of Bernstein polynomials in the real domain are developed, beginning with the proof of the approximation theorem of Weierstrass The close connexion with the theory of probability is emphasized, and some of the results, relating to monotone or convex functions or functions of bounded variation, are due to the author and have previously only appeared in the Russian journal *Mat Sbornik*

In the second chapter Bernstein polynomials are generalized and applied to the approximation of discontinuous functions of general type (integrable or measurable) The connexion with moment problems and the theory of summation is discussed, and the approximation of $f(x)$ by linear sums of powers x^{α_ν}, where $\alpha_0, \alpha_1, \ldots, \alpha_\nu,$ is a sequence such that $\Sigma\alpha_\nu^{-1}$ is divergent is studied In Chapter 3 contact is made with abstract analysis It begins with a discussion of Banach spaces and functionals, and then moment problems (with Stieltjes integrals) are considered Other topics treated are rearrangements of functions, spaces of functions and Hausdorff methods of summation The last chapter deals with the theory of Bernstein polynomials in the complex domain, and this ends with the consideration of degenerate polynomials and the connexion with the summation of power series

The author has a clear style, even if a little concentrated in places, and has covered a great deal of material in the space available The printing is excellent, as is usual with the University of Toronto Press L S GODDARD

Molecular Structure and Related Problems

Edited by Y Asami and Prof K Higasi (Monograph Series of the Research Institute of Applied Electricity, No 4 (1954)) Pp vii+140 (Sapporo Research Institute of Applied Electricity, Hokkaido University, 1954, Oxford Basil Blackwell) 25s

PROFS Y. ASAMI and K Higasi have gathered together a group of nine papers, most of which represent work in molecular structure associated with their two departments at Hokkaido University in northern Japan These articles, several of which are in the nature of reviews, were read at a symposium in Hokkaido in November 1953 They show how great is the development of theoretical and experimental chemistry in Japan

As would be expected from a country where the tropolone system was first discovered, several of the articles deal with π-electron problems But dipole moments, the hydrogen bond, the activated complex in chemical reactions, the dispersion of ultrasonic waves, paramagnetic resonance and intermolecular potentials are also included The standard of publication and printing is high The English language used is beyond reproach

Mechanics of Materials

By Prof. E P Popov. (Prentice-Hall Civil Engineering and Engineering Mechanics Series) Pp. xiv+441. (New York Prentice-Hall, Inc, 1952, London Macdonald and Co (Publishers), Ltd, 1953) 70s net

PROF E P POPOV has added another to the list of excellent text-books which are available on elementary strength of materials His object is to present the engineering undergraduate with a clear exposition of the fundamental principles of the subject He does this admirably and has evidently put much thought into the order, as well as the nature, of the topics considered

The sixteen chapters adequately cover most of the material that is usually presented in Britain under the title of 'strength of materials', as distinct from 'theory of structures' This book differs from comparable works in certain respects For example, it contains a treatment of torsion of thin-walled hollow members which is very welcome Again, the method of virtual work is presented instead of Castigliano's theorem for the solution of problems by the energy method, certainly, much can be said for the virtual work approach

The text contains plenty of examples, both worked and unworked (with answers) These problems are a main feature of the book and considerably increase its value It is unfortunate that the price of the book is so high, because it may prevent many engineering undergraduates from possessing this excellent work

SCIENTIFIC CENTENARIES IN 1955

By JOAN M EYLES

IT is a view generally held to-day, supported by vital statistics of the past two hundred years, that we tend to live longer than our forefathers That being so, the ages of five men who were in their day distinguished scientists, and a sixth who is better known as a historian, all of whom died in 1555, seem worthy of special notice , for only one of them died before the age of sixty, while another reached seventy-seven, and the historian achieved the then remarkable age of eighty-five . One wonders whether a similar group of academic men of the present century could provide a better average Yet it cannot be claimed that these men had any special advantage over their fellows One was the son of a poor workman, another had a long struggle against adversity in his early years, and most of them travelled in Europe at a time when, although some of the epidemic diseases of the Middle Ages had nearly disappeared, the ravages of plague were particularly severe in Italy, France and Germany, and typhus fever, in one form or another, was frequently epidemic

The historian was Polydore Vergil, an Italian born about 1470 in Urbino, who passed about fifty years of his life in England He deserves attention here because he was the author of the first history of inventions, his "De Inventoribus Rerum" (About the Inventors of Things), a book which appeared first in 1499 and went into something like a hundred editions, in at least seven different languages He also wrote a book on prodigies, in which he endeavoured to show that most of the prodigies he quoted could be explained on rational grounds, and those that could not be thus explained did not exist. Polydore arrived in England in 1502 as a sub-collector of Peter's Pence, and at the age of eighty he received permission to return to Italy, where he died on April 18, 1555[1] His book of inventions continued to flourish and editions appeared even in the eighteenth century He gathered his information from the Bible, the classics, and many medieval sources, and although his book is now no more than a curiosity, he can be regarded as one of the earliest to study the history of science

Not many scientific authors of the sixteenth century have had one of their principal works printed twice in the past fifty years, but this is true of Georg Bauer (1494–1555), better known by the Latinized version of his surname, Agricola, whose beautifully illustrated work on mining and metallurgy "De Re Metallica" was translated by Herbert Hoover (later President of the United States) and his wife in 1912 The woodcuts have often been reproduced, and the Hoover translation was recently reprinted. Agricola was born at Glauchau in Saxony and after studying at the University of Leipzig for two years he took a post teaching Greek and Latin at Zwickau His interests then seem to have turned towards medicine and science, and after further study, including two years in Italy, he obtained a medical degree, and in 1527 a post as doctor in the new mining town of Joachimsthal, in Bohemia Here he began to make a close study of mining methods and in 1530 published his first mineralogical work, entitled "Bermannus", written in the form of a conversation between two learned physicians and a third man, Bermannus, versed in mining lore. Soon after, Agricola left Joachimsthal and in 1533 settled in Chemnitz, a Saxon town where he was resident until his death, and where, while following his profession, he continued to study mining and metallurgy He died on November 21, 1555 , but his "De Re Metallica" was not published until the following year, the delay being occasioned, it is said, by the preparation of the numerous woodcuts It remained a standard work for nearly two centuries, and is to-day a source-book of outstanding importance

An English physician who claimed friendship with Agricola was Edward Wotton, born in Oxford in 1492 He became a Fellow of Magdalen College, Oxford, in 1516 and in 1523 went to Italy for three years, studying medicine at Padua , it was probably during this period that he met Agricola After Wotton's return to Britain he became a member of the College of Physicians and was its president during 1541–43 Later, he published a zoological work, "De Differentiis Animalium" (Paris, 1552) which, while largely a compilation from ancient authors, has been called the first systematic work in zoology Wotton died in London on October 5, 1555

Yet another medical man who died in 1555 was Jacques Dubois, also known by the Latinized version of his name, Jacobus Sylvius Born at Amiens in 1478, the son of a poor workman, he eventually became one of the leading anatomists in Paris He was a popular lecturer and attracted many students, including Vesalius and Servetus. Sylvius made many additions to anatomical nomenclature, but his merits are apt to be forgotten because Vesalius criticized his teaching Nevertheless, it was Sylvius who invited the humble barber-surgeon Ambroise Paré to dinner and discussed the latter's novel treatment of gunshot wounds, an encounter which seems to have led to the publication of Paré's first book , for later Paré wrote "Which things when I told him, the good old man requested me to publish in print my opinion concerning these things" Sylvius died on January 13, 1555, five years after he had been appointed professor of medicine in the Collège Royal.

The College Royal, later the Collège de France, was founded by Francis I in 1529, and began with two professors in Greek and Hebrew, but was rapidly extended to include chairs in medicine, mathematics and other subjects The first holder of the chair of mathematics was Oronce Fine, who was appointed in 1531. Born at Briançon in 1494, Fine's early life was a long struggle against poverty He taught mathematics in Paris, but was obliged to make and sell instruments to supplement his income, and he made a famous clock for John, Cardinal of Lorraine In 1517 he went to prison, apparently for opposing, with other professors and students, the Concordat made by Francis I with Leo X He was released in 1524 Fine was also a cartographer of note, and published a four-sheet map of France in 1538 He died in Paris on October 6, 1555

Another cartographer and mathematician who died in the same year, although much younger at the time, was Regnier Gemma Frisius (1508–55), born at Dokkum in Friesland. When a medical student at Louvain he was a friend of Vesalius, whom he assisted to rob a gallows outside the town walls, in order to further their medical studies Although

Gemma became professor of medicine at Louvain, and never left that University, his real interests lay in the realm of mathematics, and he gave private lectures in the subject, one of his pupils being Mercator Gemma was the first to suggest the method of finding the longitude by the difference of times, although the unreliability of early portable clocks made it impossible to carry out the idea until John Harrison constructed a successful chronometer two centuries later He was also the first to describe the method of elementary triangulation, illustrating his theory with an account of an actual survey, using Antwerp Cathedral as his first station. This account appeared as an appendix to Apian's "Cosmographia" in 1533[2] Gemma died when only forty-six, on May 25, 1555, and in the year of his death revealed his advanced outlook by writing a letter in which he praised the new Copernican theory He certainly deserves an important place in the history of cartography

Yet another mathematical cartographer of the period was Giovanni Antonio Magini, born at Padua in 1555, a competent astronomer and a friend of Tycho Brahe He produced a large map of Italy in 1608 and his atlas of Italy was published after his death by his son In 1617 he died of apoplexy at Bologna, where he had held the chair of mathematics since 1588

A surveyor of a somewhat different category was Richard Carew, of East Anthony in Cornwall, born on July 17, 1555, who published a "Survey of Cornwall" in 1602 Carew was a country gentleman and something of a poet, and was chosen when a lad of fourteen at Christchurch, Oxford, to debate extempore with Sir Philip Sidney, his elder by a year, before an audience of noblemen He was a member of the first Society of Antiquaries, and his Survey is a very readable account of sixteenth-century Cornwall, with many interesting details concerning the tin mines and the fishing industry Carew himself took great pleasure in a fishpond he had constructed and praised it in verse " . My fishful pond is my delight" He died in 1620

Two interesting tercentenaries are those of Pierre Gassendi and Domenico Guglielmini Gassendi, born at Champtercier in Provence in 1592, was a child of poor parents, but rose to a high position in the Church He revived the Epicurean philosophy and was an opponent of Descartes's philosophical views In astronomy he was the first to observe a transit of Mercury (on November 7, 1631) which had been predicted by Kepler, and with Mersenne he carried out the first experiments on the velocity of sound For a few years he was professor of mathematics at the Collège Royal, but his health obliged him to give up lecturing in 1647 He died in Paris on October 24, 1655

Guglielmini, born at Bologna on September 27, 1655, at first devoted himself to astronomy, and in 1685 was appointed to the chair of mathematics at Bologna In the following year he was given general supervision of the "waters of the State", in other words, of irrigation This was an important task, and led to his publishing a valuable treatise on hydrostatics The grateful Bolognese created a chair of hydrometry for him in 1694, and three years later he published a classic work on rivers, "Della Natura de'Fiumi" Guglielmini also made some important observations on the crystallization of chemical salts, work which has been evaluated recently by Prof R Hooykaas, of Amsterdam[3] He was elected a Fellow of the Royal Society in 1697 and died in Padua in 1710

Before passing on to the centenaries of 1755, we should perhaps direct attention to the death on January 17, 1705, of John Ray, a naturalist whose importance would certainly justify a two hundred and fiftieth anniversary commemoration.

The eighteenth century saw the beginning of an era of scientific expeditions, and one of the earliest of these was that organized by the Imperial Academy of Sciences at St. Petersburg, under the patronage of the Empress Anne, to explore Siberia This was the "Great Expedition" of Vitus Bering, and the principal botanist was Johann Georg Gmelin (1709–55), one of the famous German family of that name, whose "Flora Sibirica" and "Reise durch Sibirien" are monumental records of an epic journey. Like many who went on this expedition, Gmelin died while still in his prime, on May 20, 1755 Another scientific writer and traveller of this period was the physician and botanist, Pierre Barrère (1690–1755), of Perpignan, who spent three years in Cayenne and published a detailed description of French Guiana

An event which was to have considerable influence on the development of chemistry took place in June 1755 This was the reading by Joseph Black to the Edinburgh Philosophical Society of his classic paper published in 1756 as "Experiments upon Magnesia Alba, Quicklime and some other Alcaline Substances" It was not only his discovery of carbon dioxide, but also the quantitative manner in which his experiments were carried out, that make this the opening of a new era in chemistry Another interesting event of the year was the founding by the Empress Elizabeth of the University of Moscow, the first Russian university

Turning now to the bicentenaries of scientists born in 1755, we note first that of the French chemist, Antoine-François Fourcroy, born in Paris on June 15 He was not yet thirty when appointed professor of chemistry at the Jardin du Roi, where he succeeded Macquer An eloquent lecturer, he did much to popularize the new nomenclature of chemistry based on the theory of Lavoisier He was a zealous supporter of the Revolution, and in this respect his relations with Lavoisier were less happy It has been suggested that by his conduct as a member of the Convention he contributed to the death of his irreplaceable colleague—an accusation that was refuted, one should add, by Cuvier Fourcroy died in 1809, on the very day on which he had been created a count of the French empire by Napoleon

Another Frenchman who belongs to this period is Nicholas-Jacques Conté (born 1755), a mechanical genius who came to the fore during the Revolution Supplies of graphite from Borrowdale were interrupted by the war with Britain, and in 1795 he invented the process by which all lead pencils are now made, using powdered graphite and clay In 1796, when experiments were being made with balloons for military purposes, he was placed in charge of all aerostatic establishments, and when Napoleon set out with the Egyptian expedition in 1798, Conté with his balloon corps accompanied him In Egypt his inventive genius proved invaluable to the expedition, cut off from home supplies after Nelson's victory in the Battle of the Nile, and it is said he seemed able to invent immediately anything that was required. He died not long after his return to France, in 1803

Two other Frenchmen born in 1755 are Jacques-Julien de Labillardière and F. D. de Reynaud, Comte de Montlosier. The former is the botanist whose valuable collections from a South Seas expedition fell into British hands as booty of war, but were released to the French government after representations had been made by Sir Joseph Banks, then president of the Royal Society. Montlosier, well known as a political writer, was also the author of a work on the volcanoes of the Auvergne, used by Von Buch and Sir Charles Lyell; in 1828 the latter spent "three delightful days" with the seventy-four year old Count at his château near Mont Dore. Montlosier died ten years later, in 1838.

Passing to Spain, an important bicentenary is that of Don Fausto de Elhuyar, born at Logroño on October 11, 1755. Don Fausto and his brother, Don Juan José, were skilled in metallurgy and mineralogy and are noted for having, in 1783, isolated metallic tungsten from its ore for the first time. Previously they had studied at Freyberg under the celebrated Werner and at Uppsala under Bergman. Don Fausto's expenses had been paid by the Sociedad Bascongada de Amigos del Pais (the Basque Society of Friends of their Country), and in 1782 he began to teach mineralogy at the Society's new college at Vergara (founded in 1777), where J. L. Proust was already professor of chemistry. In 1788 Don Fausto went to Mexico, having been appointed director general of mines by the King of Spain. There he founded the School of Mines, which was opened in 1792 and rapidly attained great prestige. He remained in Mexico for many years, but returned to Spain after the revolution and devoted himself to the mining industry of his native land. He died in Madrid, where the centenary of his death was impressively commemorated in 1933.

Another scientist of interest to geologists is the London physician, James Parkinson (1755–1824), who practised in London and was the first to describe a case of paralysis agitans, also known as 'Parkinson's disease'. Like many medical men, Parkinson was interested in geology, and he was one of the founders of the Geological Society. His "Organic Remains of a Former World" (1804–11), a general account of fossils, was for long a standard work; indeed, in 1833 it was reprinted, although its epistolary form made it somewhat long and cumbersome.

Another author of a monumental text-book was S. T. von Sömmerring (1755–1830), whose birthplace was also that of Copernicus, the Polish town of Thorn. His large treatise on anatomy was noteworthy both for its admirable illustrations and for the fact that its author had prepared editions in German and Latin at the same time. Von Sommerring also has a place in the history of the electric telegraph, for in 1808 he designed an apparatus consisting of thirty-five glass tubes, each representing a letter or number, which could act as voltameters when connected with a voltaic pile, and so could be used for signalling messages, albeit somewhat slowly.

Other inventors of the same period were Aimé Argand (1755–1803), a Swiss physicist who designed the oil burner that took his name, and Oliver Evans (1755–1811), an American who initiated the use of relatively high-pressure steam in the United States about 1800.

In reviewing the centenaries of scientists who died in 1855, the outstanding one is certainly that of Karl Friedrich Gauss, the mathematical genius who died on February 23 of that year, aged seventy-seven. Born at Brunswick in 1777, the son of poor parents, his remarkable gifts brought him while still a schoolboy to the notice of Ferdinand, Duke of Brunswick, who himself deserves grateful remembrance for financing Gauss's subsequent education. The young man soon became renowned, first as a mathematician and then for his calculations in the field of astronomy. He was elected a foreign member of the Royal Society of London in 1804. After the death of his ducal patron, Gauss was appointed director of the Gottingen Observatory, and here he remained for the rest of his life. In the field of pure mathematics, Gauss has been ranked with Newton, and like Newton he was reluctant to publish his discoveries. Only his diary, fortunately preserved, reveals how many discoveries he anticipated. His seal, a tree bearing a few fruits, with the motto "Pauca sed matura", illustrates his attitude towards publication. He was more than fifty years old when he began his famous studies of terrestrial magnetism, and then, with his young colleague Wilhelm Weber, he founded the absolute system of measurement of electricity and magnetism. With Weber he designed the magnetometer, and in 1833 they constructed the first electromagnetic telegraph, which linked the Observatory and the Physics Laboratory at Gottingen. In 1838 he received the Copley Medal of the Royal Society for his researches. Gauss was a man of wide culture, and in the midst of all his scientific work maintained a lively interest in literature and languages. At the age of sixty-two he took up the intensive study of Russian, and within two years he had become fluent, corresponding wholly in Russian with scientific friends in St. Petersburg. Indeed, the title of 'Prince of Mathematicians' so frequently applied to him scarcely seems adequate for his wide attainments.

Two French scientists who died in 1855 were J. C. Sturm and F. Magendie. Sturm, who discovered the theorem named after him, was born in Geneva in 1803, and in 1826, with J. D. Colladon, he was the first to measure the velocity of sound in water, using a bell suspended in Lake Geneva. François Magendie, born at Bordeaux in 1783, achieved fame in a very different field. He was the creator of the experimental technique in physiology, and in his experiments upon animals acquired an unenviable reputation for ruthlessness. He is particularly noted for giving the first experimental proof of the motor and sensory functions of the spinal nerve roots, and is also remembered gratefully by physiologists for his early recognition of the genius of Claude Bernard, whom he made his assistant. Magendie died at Sannois near Paris on October 7, 1855.

Two well-known English geologists, who both died in April 1855, were Henry Thomas de la Beche, first director of the Geological Survey, and George Bellas Greenough, first president of the Geological Society. Greenough, the older of the two, was born in London in 1778. He was a leading figure in the establishment of the Geological Society in 1807, and steadfastly countered the opposition of Sir Joseph Banks, who, as president of the Royal Society, disliked the formation of a new and independent scientific society. Greenough devoted much time to assembling material for a geological map of England and Wales, which was published under the auspices of the Geological Society in 1820, replacing that of William Smith. In 1854 Greenough exhibited a large-scale geological map of India, and when he died on April 2 of the following year at the age of seventy-six, he was in Naples on his way to the east to make further researches His valuable library and maps were presented to the Geological Society, and many of his specimens are in the collections at University College, London

Sir Henry de la Beche, born in London in 1796, died shortly after Greenough, on April 13 He had become a Fellow of the Geological Society in 1817, and of the Royal Society in 1819. He made many contributions to the geology of south-west England while still a young man, and in 1831 began to colour geologically the 1-in Ordnance maps of that region His own resources being insufficient, he obtained a grant of £300 from the Treasury to carry on this work, and in 1835 received an official appointment to continue the geological survey of Cornwall This was the beginning of the present Geological Survey, and in the succeeding twenty years de la Beche fostered its growth until he was directing the work of a considerable band of skilled men, as well as supervising a Museum of Practical Geology and the attached School of Mines. He was honoured with a knighthood in 1842, and a few months before his death received the Wollaston Medal, the highest award of the Geological Society.

The month of April 1855 was also that of the death of Dr. Martin Barry (born 1802), who, after graduating as M.D at Edinburgh in 1833, took up the study of embryology. In 1840 he was elected a Fellow of the Royal Society, from which he had received a Royal Medal the previous year One of his most important observations was that of the penetration of the ovum by the spermatozoon in the rabbit

Another Edinburgh graduate who was also a naturalist was George Johnston (born 1797), a founder of the Ray Society and for many years one of the editors of the journal now known as the *Annals and Magazine of Natural History* Johnston was a resident of Berwick-on-Tweed, where he was thrice mayor, and died there on July 20, 1855. A namesake who died a few weeks later was James Finlay Weir Johnston, a Scottish chemist, who after studying under Berzelius became the first reader in chemistry and mineralogy in the University of Durham, a position which he held until his death He was also chemist to the short-lived Agricultural Chemical Association of Scotland, and the author of a "Catechism of Agricultural Chemistry and Geology", which went into thirty-three editions in five years and was translated into nearly every European language

Two other interesting centenaries are those of the chemist C B Mansfield (1819–55), and the civil engineer and inventor Bryan Donkin (1788–1855) Mansfield is noted for having found a method of extracting benzene from coal-tar, a discovery which laid the foundations of the aniline industry Donkin, in addition to many inventions in the paper-making industry, in 1812 began in Bermondsey the commercial preservation of meat and vegetables in airtight tins, a process that was welcomed by seafarers and explorers long before it revolutionized the domestic kitchen

The list of those born in 1855 is noteworthy for including three past presidents of the British Association for the Advancement of Science Sir David Bruce, one of the great pioneers of medical research, was president at the Toronto meeting in 1924 Born in Melbourne, Australia, on May 29, 1855, he studied medicine at Edinburgh and then entered the Army Medical Service in 1883 While serving in Malta he investigated the disabling Malta fever (of much wider distribution than its name implies), and in 1886 discovered the micro-organism that caused the disease, although seventeen years elapsed before goat's milk was recognized as its carrier Next, working in Africa, Bruce discovered the trypanosome that is the cause of the fly disease in cattle and horses, and later, with others, was able to prove the connexion between the tsetse fly, Gambia fever and sleeping sickness Bruce received many honours for his brilliant researches He died in 1931, only surviving by a few days his wife who had constantly assisted him in all his work

In the year following Bruce's death, 1932, the president of the British Association was Sir Alfred Ewing, born at Dundee on March 27, 1855 He had been professor of engineering in Tokyo during 1878–83, during which period he began the researches in magnetism for which he received a Royal Medal in 1895 Professor at Cambridge during 1890–1903, where he is regarded as the virtual founder of the engineering school, he resigned to take up an appointment as Director of Naval Education, and then devoted his energies to the re-organization of scientific training in the Royal Navy. To the general public he is best known for his work during the First World War in 'Room 40', where the de-coding of secret wireless messages was carried on This work was followed by a long period of office as principal of the University of Edinburgh, during which the new science blocks known as King's Buildings that are a permanent memorial to his administration were erected In 1929 he retired to Cambridge, where he died six years later.

Frederick Orpen Bower, the Yorkshire botanist who died as recently as 1948, was president of the British Association when it met in Bristol in 1930 Bower was noted both as a morphologist and for his work on the origin of the land flora, which he discussed in several books, the latest being "Primitive Land Plants" (1935) Born at Ripon on November 4, 1855, and educated at Repton and at Trinity College, Cambridge, he reversed the more usual drift south and was regius professor of botany at Glasgow for forty years He received the Darwin Medal of the Royal Society in 1938

A British physicist who was also an extremely practical experimentalist was Sir Charles Vernon Boys, born at Wing, in Rutland, on March 15, 1855 By his choice of quartz fibres for torsional suspensions he made an important step forward in technique Boys procured fibres of the requisite fineness by the ingenious method of shooting from a cross-bow an arrow attached to a heated quartz rod, and later he used these fibres in the apparatus that he designed for his classic determination of the constant of gravitation This apparatus is now in the Science Museum at South Kensington Boys, who received from the Royal Society a Royal Medal in 1896 and the Rumford Medal in 1924, died in 1944

Two others who will be remembered this year for discoveries that became of great industrial importance are C. F. Cross (1855–1935), who in obtaining viscose from cellulose in 1892 laid the foundations of the artificial silk industry, and William Friese-Greene (1855–1921), the Bristol inventor whose patent for a camera and projector, filed in June 1889, is held to support his priority over Edison in the field of cinematography.

An eminent French meteorologist, L. P Teisserenc de Bort, was born in Paris on November 5, 1855, and died at Cannes in 1913 He was a pioneer in the investigation of the upper air, using balloons carrying self-recording instruments He showed there were two divisions of the atmosphere, and named the upper isothermal layer the stratosphere

Other noteworthy centenaries are those of Bohuslav Brauner (1855–1935), the Czech chemist who after studying under Roscoe at Manchester carried out important researches on the chemistry of tellurium and the rare earths , H F Geitel (1855–1923), who collaborated with Elster in work on the photoelectric cell , and Christian Bohr (1855–1911), a Danish physiologist who made important studies in the physiology of respiration There is also Percival Lowell, born at Boston on March 13, 1855, who established the Flagstaff Observatory in Arizona Here he carried out detailed studies of Mars, as well as a number of spectroscopic studies of planets, comets and spiral nebulæ, work which remains of permanent value, even if his frequently expressed belief in the existence of life on Mars has failed to find general support

WHAT IS A VIRUS?[*]

By Dr KENNETH M. SMITH, F.R S
Plant Virus Research Unit (Agricultural Research Council),
Molteno Institute, Cambridge

THERE are two main theories on the nature of viruses , one supposes that they are parasitic organisms which have developed parasitism to the highest possible degree Laidlaw has suggested that parasites, through the indolence of living a 'borrowed life', gradually give up making substances essential for their growth because they are always at hand in the cells of the host The other theory suggests that some viruses at all events are not of external origin at all, but are derived from the cell proteins of one organism and only become viruses when transferred to the cells of another different organism I have not attempted to answer the question which supplies the title to this discourse, but leave it to the reader to choose for himself between the alternative answers to the question "What is a Virus ?"

Only the viruses affecting plants and insects are dealt with, since these have been my special study

Plant Viruses

The earliest known record of a plant virus disease, although of course it was not recognized at that time as such, is to be found in a description published in 1576 of a variegation in the flower colour of tulips This is now known to be a virus of the mosaic type Change in the colour of the flowers, or 'breaking' as it is called, is a fairly common symptom of plant virus diseases Besides the tulip, the blood-red wallflower frequently shows a yellow flecking of the petals, and this bodes ill for the grower of cabbages and cauliflowers in the district since the virus which affects the colour of the wallflower causes a severe disease in cruciferous crops

The symptoms caused by viruses in plants take a great variety of forms , besides the simple mosaic pattern on the leaves, there are other leaf changes There may be numerous concentric rings with a central spot, or leaf distortions of various kinds Sometimes the leaf blade is entirely suppressed, leaving only a string-like tendril, or again there may be outgrowths of secondary leaves from the undersurface of the leaf blade , these are known as enations Frequently the whole plant is distorted or dwarfed, with many short stems , this type of disease is known as a witch's broom In one interesting virus disease which affects leguminous plants, the chief symptom is the production of tumours which seem analogous to the various virus tumours produced in animals

Viruses attack all kinds of flowering plants, including forest trees In Great Britain the most important virus diseases are those attacking the potato, the sugar beet, raspberries, strawberries and the brassica crops In North America the virus diseases of stone fruit trees, peaches, plums and cherries, are becoming a very serious problem, and there are signs that the same problem will have to be faced in Britain also in the near future

In addition to some of the main symptoms of virus-diseased plants, one rather interesting internal change should be described In the cells of plants infected with some viruses, particularly that of the tobacco mosaic disease, there can be seen by the aid of the ordinary microscope a rather curious body with a superficial resemblance to an organism Indeed, when these bodies—*X*-bodies they are called—were first observed, they were described by some workers as the causal organism of the disease These *X*-bodies are of two kinds, amorphous and crystalline, and it has been shown recently that the crystalline inclusions are actually aggregates of the virus itself This has been done by picking out the crystal from the cell, dissolving it in a micro-drop of water and photographing it on the electron microscope (Williams and Steere[1]).

One property of plant viruses which distinguishes them from most bacterial and fungal plant pathogens is their close relationship with insects Many viruses depend entirely upon insects for their transfer from diseased to healthy plants. The insects which carry plant viruses—termed vectors—are mostly, but not all, of one kind , they belong to the order Hemiptera and are of the sap-sucking, not leaf-eating, type The commonest insect of this kind, of course, is the aphid, and many viruses are transmitted from plant to plant by these insects

There is another kind of sap-sucking insect belonging to the same order as the aphids and known as a leaf-hopper These insects are concerned, particularly in North America, with the spread of a number of important plant viruses In certain of these cases it has been proved that the plant virus actually multiplies inside the insect. This is very interesting, because a plant virus which multiplies inside an animal must have some affinities with the animal viruses It has been shown by Black[2], working in America, that a virus affecting clover is transmitted from the parent insect to its offspring He also found that the virus could be carried on for a period of four years covering fifteen generations without the insects having access to a further source of virus This shows, fairly conclusively, that the virus must have been multiplying inside the insects during that time, otherwise it would have involved a dilution of 10^{-17}, which is far greater than any virus could stand

Before concluding this brief account of the relationship of plant viruses with insects, mention must be made of an interesting virus, only recently discovered, causing the disease known as turnip yellow mosaic. This virus, curiously enough, cannot be transmitted by aphids or any other sucking insect. The vector in Nature is the common flea beetle, but in experimental studies it has been found to be transmitted by any biting insect without salivary glands. The explanation lies not so much in the absence of the salivary glands as in the fact that insects such as beetles, which lack these glands, regurgitate while feeding. In so doing, the virus which has been swallowed and which remains in the fore part of the gut for a week or more is brought into contact with the healthy leaf in the process of eating, and the new plant thus becomes infected. Thus it comes about that any biting insect which regurgitates while feeding can transmit the virus. It has been proved experimentally that such insects as grasshoppers and earwigs, which fulfil these conditions, can also transmit the turnip yellow mosaic virus.

---

[*] Substance of a Friday Evening Discourse delivered at the Royal Institution on November 12

One of the most interesting relationships between some viruses and their hosts is that of latency. Broadly speaking, this means that a virus may be present in an organism without causing a disease. A familiar example of latency is herpes simplex or 'cold sore' in man. The herpes virus remains symptomless unless stimulated by some external factors to multiply and become virulent. These external stimuli differ greatly and vary from emotional disturbances, exposure to ultra-violet light (sunlight) or the advent of another virus, for example, that of the common cold. A truly latent virus, however, never produces a disease in its host and cannot apparently be made to do so. There are two good examples of this type of latency among the plant viruses. One is invariably present in a well-known potato variety, King Edward, and no plant of that variety has ever been found free of the virus. The other occurs at certain periods of the year in a very high percentage of the commercial sugar beets, not only in Britain but so far away as Southern California. It is not possible to detect the presence of either of these viruses in their hosts except by transfer of the sap to other plants, which then do show symptoms of virus infection. The most interesting fact about these two viruses is that apparently they have no natural means of spread, and yet the latent sugar beet virus occurs in a very large number of plants without it being, so far as we know, either seed- or insect-borne. It may be, of course, that there exists a method of spread of which we know nothing, but in the meantime these two viruses lend support to the idea that some plant viruses may be normal cell constituents in one species and become a virus when transferred to another plant.

Certain plant viruses occur in such high concentration in the plant that it is possible to extract them by means of chemical precipitation methods and purify them to such an extent that they crystallize. Many plant viruses, however, because of instability or low concentration in the host, cannot be isolated in sufficient quantities, but about half a dozen have now been crystallized and the crystals may be eight- or twelve-sided, or take the form of flat plates.

It has been mentioned earlier that we now know quite a lot about the size and shape of viruses, but this could not be achieved by means of the ordinary microscope. With the electron microscope, however, it is possible to obtain a resolving power of 5 mμ, and the latest instrument is said to give a resolution of 1 mμ (10 A.). This, of course, is far smaller than any known virus, and we can now see and photograph any virus which can be obtained in a suitably pure condition. The first virus to be photographed on the electron microscope was that of tobacco mosaic—appropriately enough, since it was the first virus to be discovered. The photographs confirmed a previous belief that the particles are long rods and showed that they measure about 300 mμ in length by about 15 mμ in width. Several other plant viruses have been photographed and some of them are spherical or near spherical, whereas others are rods.

It is hoped, however, to do more with the electron microscope than observe the size and shape of viruses. It is possible now, by means of the technique of cutting ultra-thin sections of fixed material, to observe the virus inside the cells of the host.

Very little is known as to how viruses multiply, and the examination of sections of infected cells at different stages of the disease may help to solve the problem. In looking for viruses in sections of infected cells, it helps matters if the virus in question is of a characteristic shape. For example, it is easier to see the long rods of tobacco mosaic virus inside the cell than it is to find some of the very small spherical viruses. Sections of cells infected with tobacco mosaic virus show the virus particles in and around the chloroplasts.

Insect Viruses

The viruses which attack insects are for some reason the least investigated of all the virus groups. We know that there are several quite different kinds of viruses, but the majority have this in common that they attack the larval stages rather than the adults. The best known are the 'polyhedral diseases', so called because of the presence in the tissues of infected larvæ of huge numbers of polyhedral, or many-sided, crystals. These crystals have been recognized for many years and much controversy has raged about them. However, it is now known that they are not the virus itself, but the virus is contained within them. This is a point of difference from the plant virus crystals, which are actually composed only of virus particles.

It has recently been shown in our laboratory at Cambridge that there exist two entirely different and distinct types of polyhedral diseases. There is first the classical nuclear type, in which the virus starts to multiply and the polyhedra to form, inside the nuclei of cells in the tracheæ, blood and skin of the diseased caterpillar. It was shown not many years ago by Bergold[3], with the electron microscope, that if the crystals are treated with weak sodium carbonate they dissolve, leaving behind a thin membrane containing numerous rod-shaped virus particles.

In the second type of polyhedral disease, only recently discovered (Smith and Xeros[4]), the virus multiplies and the polyhedra form in the cytoplasm and not in the cell nucleus. Moreover, the polyhedra are confined to the gut of the diseased caterpillar. When this type of crystal is treated with weak sodium carbonate and photographed on the electron microscope, the result is somewhat different. The crystal only partially dissolves, leaving a honeycomb-like skeleton, and there is no residual membrane. Further work has shown that the virus particles are spherical and not rod-like, and each round virus particle fits into one of the round holes in the polyhedral crystal. We thus have the interesting phenomenon in which the shape of the virus particle is correlated with a particular type of crystal, site of

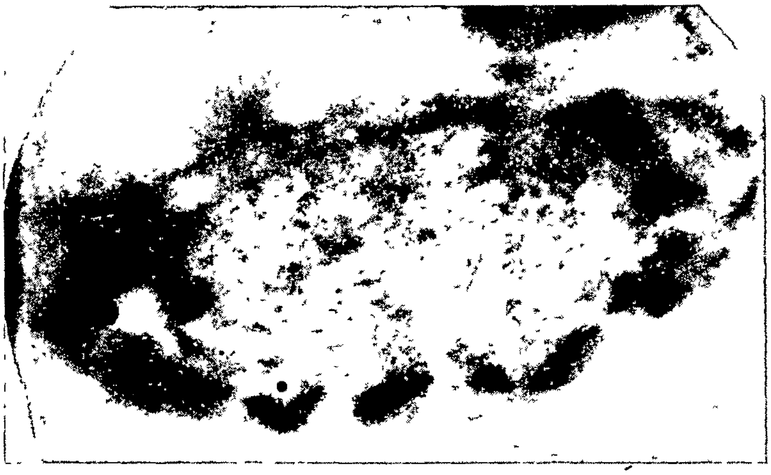

Fig 1 Thin section through a diseased blood cell of the leatherjacket (*Tipula paludosa*) showing the greatly enlarged nucleus filled with virus rods The largest of the bodies seen between the nuclear membrane and the edge of the cell is a polyhedral crystal × 1,000

multiplication and particular set of symptoms A further interesting fact is that each of these virus particles is composite, consisting of four or five extremely minute spheres (Smith and Xeros[5])

While the majority of polyhedral diseases attack the larvæ of Lepidoptera, butterflies and moths, there is one interesting virus of this type which affects the larva of the cranefly or daddy-long-legs (Diptera) This fly larva, known as a 'leatherjacket' because of its tough integument, is an agricultural pest of some importance

The virus causes a blood disease, a kind of leukæmia, and the number of blood cells is enormously increased and pack the blood cavities Towards the end of the disease the polyhedral, or rather crescent-shaped, crystals form at one end of the enlarged pathological blood cells (Fig 1) These crystals have very extraordinary properties and behave quite differently from the polyhedral crystals of the Lepidoptera When put into alkali, they become transformed into long thin threads or worm-like shapes, but when returned to water they resume their crystalline appearance Thin sections of these remarkable crystals reveal the presence inside them of many virus rods

Another type of virus disease infecting caterpillars is known as a 'granulosis' or 'capsular disease' Here the place of the polyhedral crystal is taken by numbers of very small granules, each of which contains one or sometimes two virus rods instead of hundreds as in the polyhedra A disease of this type attacks a caterpillar which is a pest of the tea bushes in Ceylon, known as the 'nettle-grub' When the granules of this disease are treated with weak alkali, the outer capsule dissolves leaving only a thin 'ghost', and inside this is a second capsule containing the virus rod The reasons for this curious 'Chinese box' arrangement are not known

A very interesting virus infecting the leatherjacket, in addition to the polyhedral virus already mentioned, has recently been discovered in our laboratory and was later briefly described by Xeros[6] This virus, the particles of which tend to have a hexagonal shape, occurs in very high concentration in the insect, and when a drop of fluid is extracted from a diseased larva the particles arrange themselves in the regular manner shown in Fig 2

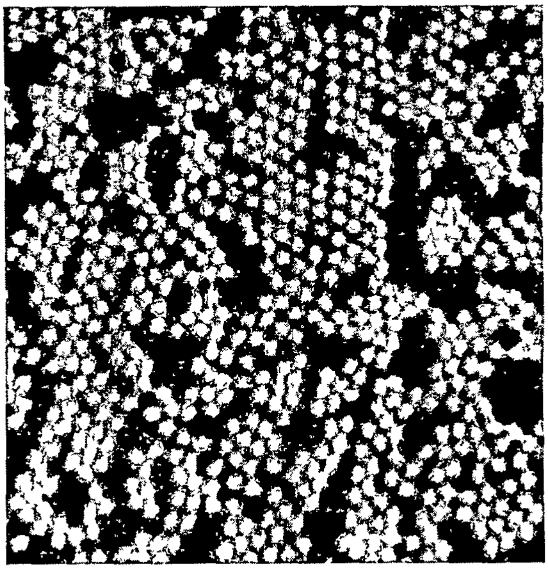

Fig 2 A drop of fluid from a leatherjacket infected with a new virus disease, note the large numbers of virus particles and their regular arrangement × 10,000

Thin sections of the fat body of an infected larva show such enormous numbers of virus particles that the whole material of the organ seems to be converted into virus The arrangement of the virus particles inside the fat body is very interesting, in addition to the large numbers of isolated particles, there occur numerous masses or agglomerations of virus particles which look superficially like some of the intracellular inclusions of other insect viruses These masses, however, appear to be composed only of virus particles (Fig. 4).

In thin sections of the virus particles themselves (Fig 3) a darker area or 'nucleus' is visible, suggesting that they may have a composite nature similar to that of the cytoplasmic polyhedral virus previously described

At the present time we know very little of the way in which viruses multiply, and it is hoped to learn more of this process by the examination of thin sections of cells under the electron microscope. The nuclear polyhedral diseases of insects, to which we have already referred, are very suitable for this kind of study Because the main initial focus of virus multiplication is in the cell nucleus, it is possible to make an intensive study of this circumscribed area From an investigation made at Cambridge on the nuclear disease of the silkworm, the following sequence of events has been built up (Smith and Xeros[7]) First, the infected nucleus enlarges greatly until it practically fills the cell Then the chromatic net or central mass begins to form, and from the edges of this, and of the chromatin lining the nucleus, the virus rods begin to appear, very much as if they were being pushed out from within At this stage there are no free virus rods in the 'ring zone' of the nucleus

It is interesting to note that as the virus rods are apparently extruded, they seem to be longer than the normal rods and can be seen dividing In the next stage many free virus rods appear, and it should be noticed that they are without the enveloping capsule which surrounds each virus rod when inside the polyhedral body When the interior of the nucleus contains many virus rods, the protein of which the polyhedral crystals are made begins to form It is, in fact, actually possible to see the virus rods being incorporated into the crystals as it forms around them In the last stage the nucleus becomes filled with the polyhedral crystals, in which are incorporated the virus rods, and there are no free virus particles visible in the nucleus At this stage the nuclear membrane bursts and the polyhedral crystals are liberated

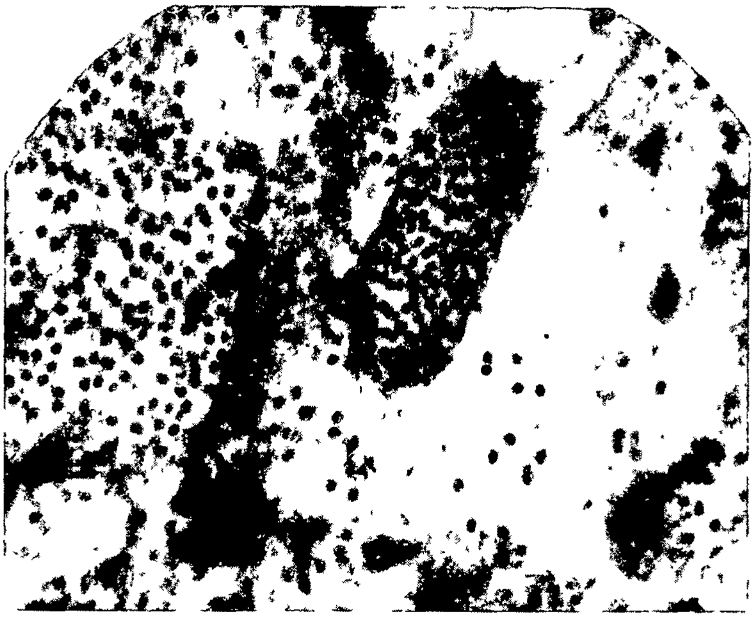

Fig 4 Section through part of the fat-body of an infected leatherjacket, note one of the many aggregates of virus particles × 16,000

Electron micrographs by S Vernon-Smith

Much the same kind of process seems to take place in the diseased blood cells of the leatherjacket Thin sections of these, when photographed in the electron microscope, reveal the enlarged nucleus containing a central body, which is often shaped like a horseshoe Around this is a second or pericentral body, while outside this again is a less dense zone in which many virus rods can be seen.

We know, therefore, from our studies so far of these nuclear virus diseases, that almost all the chromatin of the infected nuclei is organized into a central virus-producing chromatic mass or net which has a large surface area

Viruses in the Control of Insect Pests

There is a practical aspect to the study of insect viruses, and mention must be made of the possibility of using them to control noxious insect pests So far, the method used has been to breed numbers of the caterpillar pest in question and infect them with a polyhedral virus disease to which they are susceptible By this means a great quantity of polyhedra can be obtained, and these are used to start an artificial epidemic This method has been used with success in California and Canada[8,9] These were cases of controlling an insect pest by artificial propagation of a natural infection We hope, however, to take the matter further by providing a virus to attack an insect pest which does not suffer naturally from a virus disease We have shown recently that, contrary to accepted opinion, the polyhedral viruses of insects are not so specific in their action as was thought, and that cross-infection is quite possible Using a combination of two viruses originally obtained from caterpillars of the painted lady butterfly (*Vanessa cardui*), we have infected a large number of different species of caterpillars Some experiments in the control of two well-known insect pests have been made, using the same combination of viruses The pests in question are the caterpillars of the winter moth (*Operophtera brumata*) and the pine looper (*Bupalus piniarius*) Foliage of apple and pine needles contaminated with the two polyhedral viruses were fed to the larvæ The results were quite surprising, 75 per cent of the winter moth caterpillars and 100 per cent of the pine loopers were killed by a polyhedral disease Examination of the dead larvæ showed that they had died of a cytoplasmic virus disease of the gut So far as this goes, it is satisfactory, but the experiments have still to be made on a large scale out-of-doors, and methods of biological control are liable to go wrong because there are so many variable factors

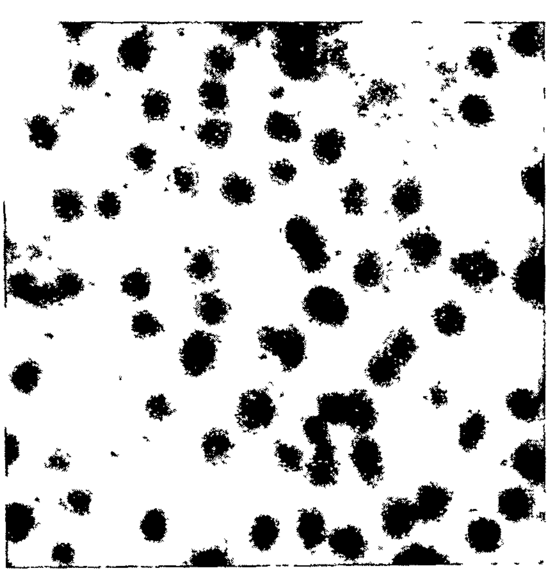

Fig 3 Section through some of the virus particles shown in Fig 2, note the darker centres in some cases, suggestive of a composite nature × 42,000

KAFUAN STONE ARTEFACTS IN THE POST-AUSTRALOPITHECINE BRECCIA AT MAKAPANSGAT

By C K BRAIN, PROF C VAN RIET LOWE and PROF R A DART

Discovery and Geology

DURING October 1954, the main breccia sections at Limeworks, Makapansgat, South Africa, were sampled for mineralogical analysis The profile of one of the most complete and interesting of these sections is reproduced in Fig 1

The 15-ft thick deposit of light pink breccia, which rests directly upon the basal travertine, has been referred to by Dart[1] as the australopithecine-bearing "grey white clays". Afterwards King[2] termed it the "Older Red Sand". A heavily calcified deposit, it contains numerous weathered dolomite blocks, as well as a band of rounded water-worn pebbles at the 40-ft level The layer as a whole can be regarded as a contaminated stalagmite, and certainly represents a very slow accumulation It is followed in sequence by 35 ft of what has been described as calcified "loess" by Bosazza, Adie and Brenner[3] in 1946 and by Dart[1] in 1947 A careful examination of this material, however, has shown that the term 'loess' certainly cannot be applied. Throughout the greater part of its depth, this layer consists of a calcified soil containing very numerous pieces of rock Almost without exception these rock pieces show signs of abrasion typical of river action, while many of them have been very effectively rounded This fact, together with the presence of water-worn quartzite pebbles derived from higher up the Makapan Valley, clearly indicates that one is dealing here with a coarse river aggradation deposited inside the cave at a time when its opening was close to river-level The present elevation of the surface of the deposit above the modern river-bed is 160 ft Considering, then, that the original cave entrance must have been rather above the present surface of the deposit, some impression is gained as to the amount of erosion which has occurred since the whole deposit was laid down

The conclusion that part of the Limeworks cave-filling represents a river gravel is a significant one But more significant still is the observation that this gravel contains stones showing unmistakable signs of artificial fracture. In view of this fact it becomes vital to establish the relationship between the gravel bed and the underlying australopithecine-bearing breccias

At Limeworks, the greatest concentration of bone is to be found in the heavily calcified breccias resting directly upon the travertine floor It is from these that all the australopithecine fossils have been obtained. Mineralogical study has shown that these breccias contain a large proportion of residual cave material, and that they formed very slowly at a time when the cave opening was small The great length of time required for their formation accounts for the concentration of bone within them These bone-rich strata may be correlated with the 'light pink breccia' in Fig 1 The transition at the 35-ft level from this breccia to the less heavily calcified gravel represents the first rapid introduction of outside material through the suddenly enlarged cave entrance It is therefore my opinion that the section shown in Fig 1 can be regarded as a single phase of accumulation, and that no major temporal unconformity occurs at any point. This conclusion was first reached on faunal grounds by Cooke[4] in 1947 when he wrote "On the percentages of extinct and living forms and the number of identical species present in the lower, middle and upper zones of the Limeworks Quarry, it is clear that there is no very great difference in age between these zones". This means, therefore, that there can be no very great age difference between the gravel deposit and the australopithecine-bearing breccia.

Consideration will now be given to the relative dating of Limeworks in comparison with the other Transvaal australopithecine sites It has been found that the most profitable approach to the problem of relative dating of the cave deposits is through an estimation of the past climates which prevailed at the times of their accumulations Such an estimation has been made possible by various mineralogical and analytical means which will be described in detail elsewhere The most direct of these is through percentage abundance determinations of wind-rounded sand grains in the breccia sands If the necessary precautions are taken, such determinations provide a direct clue to the dryness of the conditions prevailing at the times in question

The climatic deductions considered in conjunction with the faunal successions for the various sites have led to the establishment of the following sequence in time, which reads from the bottom up

Dryness	Site
Minimum—increasing	Kromdraai (2 sites)
Decreasing	Swartkrans
Maximum	Sterkfontein

In his paper on the dating of the australopithecines, Oakley[5] places Limeworks slightly earlier than

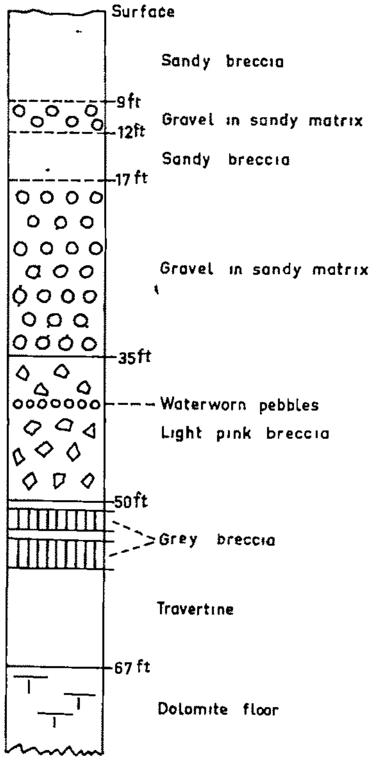

Fig 1

Sterkfontein, but the climatic indications now obtained from Limeworks show it to fall more readily somewhere between Sterkfontein and Swartkrans, but almost certainly overlapping the latter to some extent. This conclusion is supported by the faunal evidence. In considering the baboon genera *Simopithecus* and *Papio*, recent, and as yet unpublished, work by Freedman has shown that neither occurs at Sterkfontein, that the former is present at Limeworks, while both have been obtained from Swartkrans. Likewise, *Equus* does not occur at Sterkfontein but has been found at both Limeworks and Swartkrans.

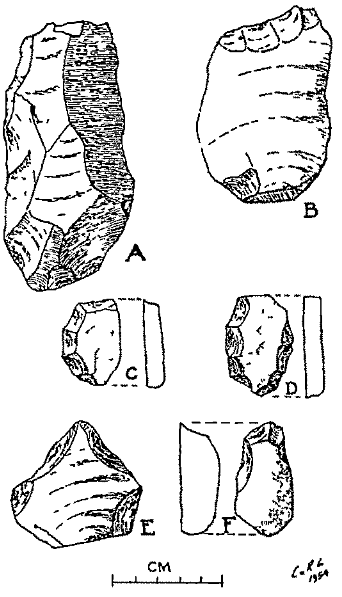

Fig 2

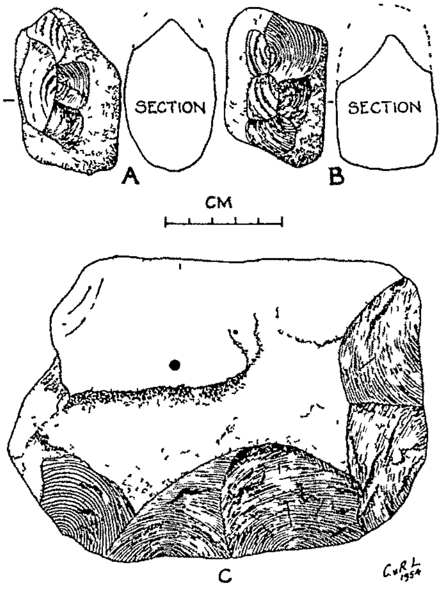

Fig 3

The complete evidence for the position of the sequence Sterkfontein – Limeworks – Swartkrans – Kromdraai in the Pleistocene time-scale will be considered in detail elsewhere. It may be stated, however, that this evidence is not in full agreement with Oakley's[5] Kageran–Kamasian date for the sites, but tends to indicate both their greater antiquity, and the presence of an extra pluvial period to which no African stage-name can at present be applied.

To sum up, it has been suggested that in the Limeworks deposit one is dealing with a coarse river aggradation superimposed directly upon the australopithecine horizon, that there is no significant temporal unconformity between these horizons, and that the whole succession is comparable in age with the Sterkfontein–Swartkrans sequence. It has also been stated that stones showing possible artificial fracture were obtained from the gravel bed. These were all taken from the basal five feet of the gravel, from, in fact, the 30–35 ft. level of the profile in Fig. 1. They come, therefore, from a position directly above the australopithecine horizon, and were submitted for examination by Prof. van Riet Lowe, whose conclusions concerning them may now be presented.

C. K. B.

The Artefacts

Of the 129 trimmed, utilized or damaged stones Mr. C. K. Brain submitted to me from the gravels that overlie the australopithecine-bearing breccias at the Limeworks site in the Makapan Valley, only seventeen are undoubted artefacts. Of these, fifteen are of deeply leeched dolomite, one of vein quartz and one of dark grey quartzite. They include ten flake artefacts, four pebble artefacts, two artefacts on thin slabs of dolomite and one split pebble.

The artefacts on flakes include those illustrated in Fig. 2 (*A*, *B* and *E*). *A* and *B* were struck from cores only *after* other and possibly similar flakes had been struck. *B* was later trimmed into an end-scraper, and *E* into a double-notch-and-tooth type of tool.

The four artefacts on water-worn pebbles include the two tools illustrated in Fig. 3 (*A* and *B*), the large core shown in Fig. 3 (*C*) and the split pebble illustrated in Fig. 2 (*F*). *A* and *B* are as typical of the Oldowan as they are of the Kafuan Culture, but *F* is decidedly Kafuan.

At least seven flakes were deliberately removed from the large core (Fig. 3, *C*): five in one direction, in the typical block-on-block manner, and two in the opposite direction.

The artefacts on thin slabs of dolomite (Fig. 2, *C* and *D*) show steep secondary, almost vertical, trimming around their peripheries in the best 'Hope Fountain' manner.

The split pebble (Fig. 2, *F*) was split longitudinally down its major axis in the manner of an ortholith and trimmed into a beaked or rostro-carinate form (Stage I) typical of the Developed Kafuan Culture[6].

On the evidence before us, this assemblage can only be assigned to the Developed Kafuan Culture as this occurs in Uganda and in the disturbed upper layers of the Basal Older Gravels in the 200-ft. terrace of the Vaal River at Klipdam[7].

The discovery of Kafuan-type artefacts in a terraced river gravel in an undisturbed stratified sequence of deposits immediately overlying australopithecine-bearing breccias in a cave is unique. When we add to this the known occurrence of Chellean- and Acheulean-type tools that cover the full range of the great African Hand-axe Culture of the Earlier Stone Age of Middle Pleistocene times in more recent deposits in, and in the immediate vicinity of, this amazing valley, some in caves and some in exposed sites, followed stratigraphically by Middle and Later Stone Age remains of Upper Pleistocene and Holocene times, we are encouraged to hope that the establishment of a Quaternary chronology independently of any set up elsewhere is, among other things, now well within our reach.

C. v. R. L.

General

Nearly thirty years ago the Makapansgat Limeworks bone breccia was recognized as a site of early human occupation[8]. Twelve years later, Early Stone

Age implements were found about a mile farther up in the same valley in the sealed Cave of Hearths deposit[9] The general stratification of the Limeworks breccia, the basal grey layer of which afterwards yielded repetitive discoveries of *Australopithecus prometheus* and the concomitant fauna, was described at the first Pan-African Congress on Prehistory at Nairobi[1]. Up to the present time, as at all other australopithecine sites, no stone artefacts have been found in the grey breccia or in the superincumbent 25–50 ft of lime-consolidated cavern deposit

The 40–60 ft of consolidated and semi-consolidated cavern breccia overlying the stalagmitic floor at the Cave of Hearths has been completely excavated since 1947 through the generosity at the outset of the late Dr Bernard Price and latterly of the Wenner-Gren Foundation. This excavation has furnished a continuous stratigraphical story of human habitation and cultural progression from the Earlier Stone Age of Middle Pleistocene times through the Middle and Later Stone Ages to the recent coming of Bantu and European

During September and October 1954, however, Mr C K Brain, in the course of the comparative mineralogical survey of the known australopithecine breccias which he has been enabled to undertake by a subvention from the Wenner-Gren Foundation, extracted from the first 5 ft of the gravel beds overlying the grey breccia in the south-eastern section of the deposit a number of dolomite stones that appeared to him to have been intentionally flaked

The Kafuan pebble culture of Uganda, so named by Wayland[10] from artefacts found in the terraced gravels of the westward-running Kafu affluent of Lake Albert, is the earliest and most primitive stone culture known in the African continent[6] Farther south in Uganda it occurs in its Earliest Kafuan form in the 270-ft terrace of the eastward-running Kagera affluent of Lake Victoria The Developed Kafuan, while the oldest and most primitive stone culture known in South Africa, first appears in Uganda in the later 200-ft. terrace of the Kagera River (*vide* ref 6)

The only implemental evidence hitherto found accompanying australopithecine remains are the fractured and worn bones, jaws and horns, that Dart claimed as the by-products of their predatory habits This discovery of Kafuan-type artefacts in a gravel bed in a stratified sequence of deposits immediately overlying the grey stratum, which nearby in the same cavern system is an australopithecine-bearing bone breccia, is unprecedented It opens up the astonishing prospect that Makapansgat may place within our grasp in a single South African valley a continuous story of human handiwork and a consecutive chronology of mankind from the dawn of the Pleistocene to the present day

OBITUARY

Prof Enrico Fermi, For Mem R S.

THE news of the death on November 28 of Enrico Fermi came as a shock to his numerous friends, many of whom had seen him only a few months previously in his customary strength and good humour. By the public at large he will be remembered as the man who opened the gates to the atomic age he led the team which, on December 2, 1942, produced the first self-sustained nuclear chain reaction—the first 'atomic pile' But he had been a leader in the field of nuclear physics long before that A few months after Irène and Frédéric Joliot had discovered artificial radioactivity in 1934 he showed, with his collaborators at the University of Rome, that neutrons can be used to produce radioactive isotopes of nearly all nuclei For a year or two thereafter any nuclear physicist who could read Italian was in great demand—he had to translate the short communications which appeared in the *Ricerca Scientifica*, nearly every one revealing some new and startling phenomenon The discovery of 'slow neutrons', of their strong absorption in selected elements such as cadmium, their ability to disintegrate boron, releasing energies millions of times their own, their diffusion in paraffin wax, the selective absorption of different neutron 'groups' in different elements seldom has there been such an explosive outburst of brilliant, wholly unexpected discoveries

Of special significance was the observation that neutron bombardment of uranium caused the formation of active products which Fermi thought were trans-uranic elements In this he was wrong, they were fission products, elements lighter than uranium, but this was not realized until four years later. So it might be said that Fermi was the first to cause and observe nuclear fission, though he did not recognize it

All this was the work of a superb experimenter, quick to design relevant tests with simple means, yet equally capable of conducting the wide-flung research and development which led to the first atomic pile. These achievements alone would have secured Fermi an honourable place in the history of experimental physics

But actually Fermi started his career as a theoretician, and it is for his work in theory that his name will be remembered through household words such as the Fermi statistics, the Fermi theory of beta-decay, and the 'fermion' (any particle which obeys Fermi statistics) It was in 1926 that he applied Pauli's exclusion principle to systems of many identical particles (Dirac did the same independently a little later), and developed the peculiar kind of statistical mechanics required to describe the thermal properties of such systems In ordinary gases the deviations from 'classical' statistics are irrelevant except at very low temperatures. But Fermi statistics gave the clue to the behaviour of electrons in metals here was a 'gas' for which even white heat represented a very low temperature, and a great many puzzling facts—such as the absence of any considerable contribution from the conduction electrons to the specific heat—fell into place when Sommerfeld (1928) used Fermi statistics to create the modern theory of electrons in metals

Fermi's theory of beta-decay was published in 1934 Again it was based on an idea of Pauli the idea of postulating a 'neutrino'—a light, neutral and practically unobservable particle—to account for the variable amounts of energy missing in beta-disintegrating processes The theory was immediately successful it accounted for most of the facts then known and predicted new ones which were duly verified Some refinements—which fitted naturally into the original framework—were added later, and it is now certain that Fermi's theory gives a correct account of all aspects of the beta-process—the mutual transformation of protons and neutrons—though the place of this process in the general scheme of things is still one of the main mysteries of to-day's physics

After the War, Fermi returned to academic work at the University of Chicago The atomic piles he had created were powerful sources of neutrons, and he used them in the experimental attack on fundamental problems, in particular that of the interaction of neutrons and electrons But he did not neglect theory his work on the origin of the cosmic radiation (1947), on the production of multiple mesons (1950) and on the interpretation of meson-scattering experiments at the big new synchro-cyclotron was witness to the unabated vigour of his mind

Born in 1901, Enrico Fermi was quick in establishing his position professor in Rome by 1928, member of the Accademia d'Italia in 1929, Nobel Prize in 1938 Since 1938 he had lived in the United States, with his wife and two children

Fermi's strength was not subtlety or high-flown imagination, but strong common sense combined with perfect mastery of his subject No vagueness or mysticism for him the essence of his work was clarity His papers were written in a style so crystal-clear that the tremendous intellectual effort which had created them was out of sight. His lectures were perfectly planned and delivered· with the skill and humour of a showman His personality, unassuming yet dominant, often provocative but always tolerant, forceful and yet easy-going, will be remembered by all who met him His joy of living was contagious, and his death is a great loss both to the world of physics and to his many friends all over the world.

O R FRISCH

NEWS and VIEWS

Directorship of the Royal Horticultural Society's Gardens: Dr H. R. Fletcher

DR H. R. FLETCHER, director of the Royal Horticultural Society's Gardens at Wisley, has been appointed to succeed Dr J. M Cowan as assistant to the Regius Keeper of the Royal Botanic Garden, Edinburgh. Dr Fletcher graduated at Manchester in 1929 and in the same year was appointed assistant lecturer in botany in the University of Aberdeen under the late Prof Craib There he became interested in taxonomy, especially in the flora of Siam. After taking the degree of doctor of philosophy, he was appointed to the staff of the Royal Botanic Garden, Edinburgh, in 1934 There he continued his work on the Siamese flora and graduated doctor of science in 1939 In collaboration with Sir William Wright Smith he has published a long series of papers on the sections of the genus *Primula* in the *Transactions of the Royal Society of Edinburgh*, the *Transactions of the Botanical Society of Edinburgh* and in the *Journal of the Linnean Society*. Then followed a revision of the genus *Omphalogramma* and numerous articles in scientific and horticultural journals on the genera *Codonopsis, Cremanthodium, Aconitum, Potentilla* and *Incarvillea* In 1951 Dr Fletcher left Edinburgh to become director at Wisley After some four years there, he is again strongly attracted to the line of work he pursued for so long at Edinburgh and is returning there shortly.

Mr F. P. Knight

MR F P KNIGHT, who is to succeed Dr Fletcher as director at the Royal Horticultural Society's Gardens, is a Devonian, fifty-two years of age, who commenced his horticultural career in 1915 at Werrington Park, Launceston, Cornwall, at that time owned by Mr J C Williams, who did so much to support George Forrest in his botanical exploration work in Western China. During 1919–23 Mr. Knight was a probationer gardener in the Royal Botanic Garden, Edinburgh, where he worked mainly in the Propagating Department, and helped with the experimental work on plant propagation from cuttings The experience gained laid the foundation of Mr Knight's favourite branch of horticulture. After a period of nearly two years as a student gardener at Kew, he was for four years in charge of the Arboretum nurseries there This was followed by a period with Messrs Baker's, of Codsall, Wolverhampton, where he specialized in the commercial production of large quantities of rock garden plants, and also supervised the firm's landscape planting activities for two years He then went to Knap Hill Nursery, Ltd, Woking. In 1940 Mr Knight was appointed horticultural officer to the Directorate of Camouflage, Ministry of Home Security, becoming senior officer as the work developed. In April 1944 Mr Knight joined Messrs. R C Notcutt's Nursery, Woodbridge, as general manager, and in 1945 was appointed managing director Mr Knight has been active in the Royal Horticultural Society, serving on the Society's Floral Committee and the Camellia and Rhododendron Committee He has been a member for several years of the Technical Sub-Committee of the Roads Beautifying Association

American Society of Tropical Medicine and Hygiene Awards

THE following awards were recently presented at a meeting of the American Society of Tropical Medicine and Hygiene:

LePrince Award to Prof. B G. Maegraith, professor of tropical medicine in the University of Liverpool. The award consisted of a medal and a prize of 500 dollars contributed by the Michigan Chemical Co. Mr J A LePrince, after whom the award is named, also received the medal, which had not been struck at the time he was first honoured by the National Malaria Society

Bailey K. Ashford Award for research on chemotherapy of malaria and amœbiasis to Dr Joseph Greenberg, of the Laboratory of Tropical Diseases, National Microbiological Institute, National Institutes of Health, Bethesda, Maryland. The award is given to a scientist less than thirty-five years of age and consists of a medal and a prize of 1,000 dollars, furnished by Eli Lilly and Co, Indianapolis, Indiana

Theobald Smith Medal to Dr George Cheever Shattuck, professor emeritus of tropical medicine at Harvard University.

The Charles Franklin Craig Lecture was given by Dr Albert B Sabin, research professor of pediatrics, University of Cincinnati Medical School

Institute of Metals : Medal Awards

The Institute of Metals has awarded the following Medals *Institute of Metals (Platinum) Medal,* for 1955, to Dr C. J. Smithells, director of research of the British Aluminium Co , Ltd , Gerrards Cross, in recognition of his services to metallurgical science, to the metal industries and to the metallurgical profession , *Rosenhain Medal,* for 1955, to Dr W A Baker, research manager of the British Non-Ferrous Metals Research Association, London, in recognition of his outstanding contributions to knowledge in the field of physical metallurgy, with special reference to the influences of gases and shrinkage on the soundness of cast metals , *W H A Robertson Medal and Premium,* for 1954, to Prof H Ford and Mr J G Wistreich, for their paper on problems of the control of dimensions, shape and finish in the rolling of sheet and strip and in the drawing of wire (*J Inst Met*, 82, 281 , 1954)

Polarographic Society: Inaugural Meeting

The inaugural meeting of the Polarographic Society was held on November 9 in the Lecture Theatre of the Pharmaceutical Society of Great Britain, 17 Bloomsbury Square, London, W C 1, with Mr W J Parker in the chair The meeting was attended by more than forty people interested in the subject, who had come from many parts of Britain Mr Parker reviewed the steps leading to the formation of the Society According to the constitution, the objects of the Society are "to advance and promote the science of polarography in all its aspects and to provide educational facilities in polarography through discussion and any other medium" He said that the Society also hopes to facilitate the discussion of day-to-day problems as well as further an understanding of the basic principles In referring to the enthusiastic support given to the new Society by the "polarographic profession", Mr Parker stressed that membership is open to any person interested in the objects of the Society , the annual subscription has been fixed at 10*s* Four papers were then presented which in themselves epitomized the objects of the Society they were "A Brief Introduction to Polarography", by Dr A L Glenn lecturer in pharmaceutical chemistry in the School of Pharmacy, University of London , "The Polarograph with Derivative and Phase Selective Additions", by G L Young, Research Department, Cambridge Instrument Co , Ltd , "Potential Pitfalls in Practical Polarography", by Mrs B Lamb, chief chemist of Tinsley (Industrial Instruments), Ltd , and "The Application of Polarography to Pyrimidine Chemistry", by Mrs N Luthy, of Stanford University, Stanford, California (now working at the University of Manchester on a grant from the British Empire Cancer Research Fund) Further information about the Polarographic Society can be obtained from V. S Griffiths, Chemistry Department, Battersea Polytechnic, London, S W.11

Courses in Advanced Technology in Britain

Following up the statements in Parliament on higher technological education (see p 22), the Minister of Education, Sir David Eccles, gave in a written answer on December 14 the names of twenty-four technical colleges in which courses in advanced technology had been approved for an increased grant of 75 per cent under Circular 255 Eight of these are in London The remaining colleges include the Birmingham College of Technology, Bradford Technical College, Cardiff College of Technology and Commerce, Huddersfield Technical College, Leicester College of Technology and Commerce, Manchester College of Technology, Nottingham and District Technical College, Royal Technical College, Salford, and North Staffordshire Technical College, Stoke-on-Trent Ninety technical colleges had applied for this grant , sixty-three had not qualified for it, and three requests are still being considered

University of Leeds Publications and Theses during 1951–52

Under the title "Publications and Titles of Theses, 1951–2" (pp 57 , 1954 , 6*d*) the University of Leeds has issued a pamphlet listing by faculties (and including the Institute of Education, the Department of Adult Education and Extra-mural Studies, and the Library) the publications of which members of the University are authors or joint-authors, and which appeared in print during October 1, 1951–September 30, 1952 Titles of theses accepted by the University during the same period for the degrees of master and doctor are similarly listed in an appendix There is an index of authors It is proposed to issue similar pamphlets for subsequent academic years

International Commission on Zoological Nomenclature Elections

The International Commission on Zoological Nomenclature announces the election of the undermentioned zoologists to be members of the International Commission on Zoological Nomenclature, with effect from the dates stated K H L Key, principal research officer, Division of Entomology, Commonwealth Scientific and Industrial Research Organization, Canberra, in succession to Joseph Pearson (resigned) (October 15, 1954) , Alden H Miller, professor of zoology and director of the Museum of Vertebrate Zoology, University of California, Berkeley, in succession to J L Peters (deceased) (October 29, 1954) , Ferdinand Prantl, vice-director, Národni Museum, Prague (October 30, 1954) , Wilhelm Kuhnelt, professor in the Zoological Institute of the University, Vienna (November 6, 1954) , F S Bodenheimer, professor of zoology, Hebrew University, Jerusalem (November 11, 1954) , Ernst Mayr, Alexander Agassiz professor of zoology at Harvard College, Cambridge, Mass. (December 4, 1954) , Enrico Tortonese, professor of zoology, Istituto e Museo di Zoologia, Universita di Torino, Italy, in succession to Prof Lodovico di Caporiacco (deceased) (December 16, 1954)

Colonial Service : Recent Appointments

The following appointments have recently been made in the Colonial Service D J Billes (senior agricultural officer, Gold Coast), assistant director of agriculture, Gold Coast ; I S Hutcheson (agricultural officer, Bechuanaland Protectorate), director of agriculture, Bechuanaland Protectorate , E M Brown (senior assistant conservator of forests, Jamaica), conservator of forests, Jamaica , I E M. Watts (meteorological officer, Singapore), assistant director, Malayan Meteorological Service, Singapore , H W Hockin (inspector of mines, Federation of Malaya), senior research officer, Department of Mines, Federation of Malaya , P T Nelson, agricultural officer, Nigeria , Mrs W M H Sesseler, government chemist, Gold Coast , N V. Williams, fisheries officer, Nigeria A J T Bayles, assistant conservator of forests, North Borneo , G J. Journeaux, assistant conservator of forests, Nyasaland , B. P Singh, assistant conservator of forests, British Honduras , C K Burton and J H Duncan, geologists, Federation of Malaya , O von Knorring, chemist, Geological Survey, Federation of Malaya , A F Trendall and J Walsh, geologists, Uganda , W. G C Bearcroft, medical research officer, West Africa Virus Research Institute, Nigeria , A R Jenkins, senior scientific officer, East African Tsetse and Trypanosomiasis Research and Reclamation Organization, East Africa High Commission , B. A. Mitchell, scientific officer, Federation of Malaya , T. Owens, veterinary officer, Northern Region, Nigeria , W G C Parker, veterinary officer, Somaliland Protectorate.

Electromagnetic Wave Theory Symposium in Ann Arbor, Michigan

An international symposium on electromagnetic wave theory, sponsored by Commission VI of the International Scientific Radio Union and the University of Michigan, will be held in Ann Arbor at the University of Michigan during June 20–25 Five topics will be considered propagation in doubly refracting media in wave guides (for example, ferrites) , boundary-value problems of diffraction and scattering theory , work in antenna theory of fundamental importance , forward scattering , and multiple scattering (that is, of light by colloidal particles) Developments at millimetre wave-lengths will be particularly considered Anyone wishing to read a paper should submit by March 31 an abstract of not more than two hundred words to the chairman of the symposium, K. M. Siegel, Willow Run Research Center, University of Michigan, Ypsilanti, Michigan Further information on all other points can be obtained from J. W Crispin, jun , at the University of Michigan, Ann Arbor, Michigan.

The Night Sky in January

Full moon occurs on Jan 8d 12h. 44m , U.T., and new moon on Jan 24d. 01h 06m The following conjunctions with the moon take place Jan 9d 03h , Jupiter 2° N. , Jan 18d 03h , Saturn 6° N , Jan 20d 0h , Venus 6° N , Jan 25d 16h , Mercury 5° S , Jan 29d 05h , Mars 6° S In addition to these conjunctions with the moon, Jupiter is in conjunction with Pollux on Jan 24d. 21h , Jupiter 6 3° S. Mercury sets an hour after the sun on January 15 and 1h 40m after sunset on January 31, but is too close to the sun in both cases to be favourably seen Venus is a morning object, its times of rising being about 4h 20m up to the middle of the month and 4h 45m at the end of the month Its stellar magnitude varies from −4 3 to −4 and the visible portion of the illuminated disk from 0 348 to 0 528 Mars sets about 22h 25m throughout the month, and, as its declination increases from −5° to nearly 5°, it is becoming better situated for observation in the northern hemisphere It is not very close to any bright star, but its eastward movement from Aquarius into Pisces is obvious during the month Jupiter, which rises early in the afternoon (at 15h on January 31), is visible throughout the night and morning hours, stellar magnitude −2 2. Its westward movement in Gemini as it approaches δ Geminorum is easily seen Saturn is a morning object, rising at 3h 45m , 2h 55m and 2h on January 1, 15 and 31, respectively. Its declination is about 16° S., and it does not attain a great altitude in the British Isles , its apparent eastward movement towards γ Libræ continues until the beginning of March Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich Jan. 4d. 15h. 45 8m , ζ Ari (*D*) , Jan 6d 21h 04 9m , 121 Tau (*D*) , Jan 27d 18h 46 0m , ϰ Psc. (*D*), where *D* refers to disappearance The earth reaches perihelion on January 4, its distance from the sun being then a little less than 91½ million miles The Quadrantids meteors attain their maximum on January 3

Announcements

Dr S J Folley, head of the Physiology Department, National Institute for Research in Dairying, Shinfield, has been elected a corresponding member of the Société de Biologie of Paris

Dr T Robertson, assistant director (England and Wales) of the Geological Survey and Museum since 1949, is to retire on March 31 after thirty-eight years with the Survey He will be succeeded by Dr F. M Trotter, who is at present district geologist in charge of the Manchester office of the Geological Survey , and Mr J V Stephens will become district geologist at Manchester

Mr J Lamb, director of the Tea Research Institute, Ceylon, has been appointed director of the West African Cocoa Research Institute, in succession to Mr J. West, who has retired Mr. Lamb is taking up his new post in the latter part of 1955

The Society for Psychical Research is offering a prize of £50 for an essay, preferably not exceeding three thousand words, on any topic relevant to the work of the Society. Entries close on June 30 Further information can be obtained from the Secretary, Society for Psychical Research, 31 Tavistock Square, London, W C 1

The Population Council, Inc , of New York, is offering further fellowships for advanced training in the study of population at the predoctoral and postdoctoral levels. Fellowships will be available for study in universities in the United States and elsewhere for the academic year 1955–56, preference being given to qualified applicants from countries other than the United States and Europe The basic stipend of 2,500 dollars per annum may be increased by allowances for travel, dependants, etc. Application forms (to be returned by March 1) and further information can be obtained from the Population Council, Inc , 230 Park Avenue, New York 17, New York

R303

The Exhibition of Israeli Scientific Papers at the Israeli Consulate, 18 Manchester Square, London, W 1, which was to have closed on December 22 will remain open until January 7

The Wellcome Historical Medical Museum, which for the past seven years has been carrying on its activities at 28 Portman Square, London, W 1, has now removed to the Wellcome Research Institution at 183–193 Euston Road, N W 1 Exhibitions dealing with primitive medicine and with child-welfare through the ages are open to the public in the new premises (Monday to Friday, 10 a m –5 p m)

HIGHER TECHNOLOGICAL EDUCATION IN GREAT BRITAIN

In replying to a question in the House of Commons on November 23 regarding higher technological education, the Chancellor of the Exchequer, Mr. R. A. Butler, said he had nothing to add to his statement of July 13; but when pressed with regard to the position in Wales, he indicated that he intended making a further statement which would give a broader picture than that which he had given previously. This promise was repeated by Sir David Eccles, the Minister of Education, when replying to questions on this subject, in the debate on the Queen's Speech on November 30, arising out of the reference in that Speech to the Government's intention to "stimulate the expansion of facilities for higher technological education, so that advances in scientific research may be matched by increased industrial efficiency and production". Sir David dealt particularly with questions on technical education from Mr. Malcolm MacPherson, who suggested that within the Ministry of Education a division should be set up dealing specifically with technical and technological questions. Sir David agreed that there is real urgency to treat technical education as a major problem, and he announced the lifting of restrictions as to the industries for which new technical education facilities could be provided. The amount of new work which could now be started for technical education would be increased by about £2½ million a year. He added that the Secretary of State for Scotland is also anxious to see more rapid development of facilities for technical education and will be letting the education authorities concerned have details of his proposals shortly.

The promised statement was made in both Houses of Parliament on December 7. In the House of Lords, the Lord President of the Council, Lord Salisbury, stated that the Government's plans provide for the massive expansion of the Imperial College of Science and Technology, London, and for major developments at Glasgow, Manchester, Leeds and Birmingham, including also developments on a fairly large scale at Cambridge and Sheffield, and specialized developments at other centres in Great Britain, notably at Edinburgh, Newcastle, Southampton, Nottingham and Swansea. Some of them are to be financed by industry and some by Treasury grants. The Government is endeavouring to avoid either excessive centralization or undue dispersal of resources, and is concentrating its efforts on institutions which are already receiving Treasury grants. In its view, higher technological education must be closely linked with other university studies, and those who are studying technology should work closely with those who are occupied with the more fundamental problems of science and with its application in other fields. The problems of technology are the problems of human relations as well as of science, and in training for industry the humanities have an important part to play. Where a technological institution and a university are associated, as in London, Glasgow and Manchester, this linking of studies could be achieved. If, however, new universities are to be established in other centres by upgrading the technical colleges, it will be necessary to provide them also with additional departments, and the nation cannot afford the necessary resources of teachers, buildings and money. Accordingly, Lord Salisbury indicated that the Government does not propose to start entirely new technological institutions; but it will seek close association between the universities and industry, and it has been encouraged by the recent founding of new chairs in technological subjects with funds raised from industry. Lord Salisbury added that the universities are becoming more responsive to industrial needs by designing post-graduate classes to meet particular local requirements and by inviting industry to assist with instruction.

About one-eighth of the total recurrent grants to the universities are used for technology, in the narrower sense of the term, or about £3 million a year. Additional recurrent grants for technology, amounting to £196,000, have been made for the present academic year; these will be increased to £404,000 next year and to £704,000 for the academic year 1956–57. This will be in addition to the extra cost of salaries announced in November. For building and equipment the capital expenditure and liabilities against public funds incurred in recent years for technology, in the narrow sense, now amount to about £10 million, including a number of projects authorized last July. Further building has been authorized to the extent of £1 million, in addition to the normal university building programme for the year 1955–56, and the Chancellor will be prepared to consider, for starting in the following year, other technological projects included in the University Grants Committee's plans for developments beginning in the quinquennium. The total capital cost of this project over ten years may well be about £15 million.

With regard to the expansion of the Imperial College of Science and Technology in London, Lord Salisbury stated that building work is already in progress on the northern part of the site in South Kensington to the extent of about £1.2 million, including equipment. Further progress will soon require the release of some other parts of the site from their existing use, and the Chancellor of the Exchequer has now authorized new building work to proceed in Bloomsbury to enable existing University of London activities (such as the Warburg Institute) to be transferred there in due course from South Kensington. Approval has been given for the erection of part of the north section of the British Museum (Natural History) and the completion of the new centre block of the Science Museum to release accommodation now occupied by the Aeronautical Collection of the Science Museum. To minimize the disturbance of the Indian Collection of the Victoria and Albert Museum, plans have been approved which will enable a substantial part of this Collection to be permanently on view in the main building of the Museum. Alternative accommodation will be needed eventually for that part of the Royal College of Art which is housed in the same building as the Aeronautical Collection. The Government is still considering the future of the Imperial Institute, and it is hoped to reach an early decision.

In reply to a question in the House of Commons on December 14, regarding the development of the Royal Technical College, Glasgow, into a technological university, the Secretary of State for Scotland, Mr. J. Stuart, said that the Government believed that the progress of higher technological education in Glasgow could best be served if the College and University worked out a relationship which, without hampering the development of the College, enabled their work to be co-ordinated. The Government had invited the two institutions to enter into discussions with the view of evolving a satisfactory scheme.

COUNCIL OF SCIENTIFIC AND INDUSTRIAL RESEARCH, INDIA

THE Council of Scientific and Industrial Research, India, was established in 1942 to administer the Industrial Research Fund, created to foster industrial development in India. The Council was charged with the promotion and co-ordination of scientific and industrial research in India, including the institution and financing of specific researches and with encouraging the utilization of the results of such researches. Its functions also include the establishment or assistance of special institutions or departments for specific studies of particular industrial problems, the award of research studentships and fellowships, the establishment and maintenance of laboratories, workshops, institutes and organizations for further scientific and industrial research and their utilization, the collection and dissemination of information and the publication of scientific papers. The development of the Council's work and its present activities are clearly and attractively set forth in a volume just issued by the Council* and which does ample justice to the energy and foresight which the Council has brought to bear for the past twelve years on problems of scientific and industrial development in India.

The development of the Council's work from that of the Industrial Intelligence and Research Bureau established in 1935 is described in an introductory chapter, including an account of the work of the Research Planning Committee appointed in 1943 and of the First Reviewing Committee of 1947, out of the recommendations of which came the National Research Development Corporation (1953) and the Board of Engineering Research (1950). The general organization of the Council, its advisory bodies and laboratories is outlined in the second chapter of the volume, and this is followed by a concise account of the work which has been carried out or is in progress in the laboratories for which the Director of Scientific and Industrial Research is responsible. The next hundred pages of the report are occupied by an account of the research programmes of the various national laboratories, which include the following (dates of opening given in brackets): National Physical Laboratory of India, New Delhi (1950); National Chemical Laboratory, Poona (1950); National Metallurgical Laboratory, Jamshedpur (1950); Fuel Research Institute, Jeelgora (1950); and the National Botanic Garden, Lucknow (1953). The total is brought to fifteen by the following institutes dealing with particular branches of applied science: Central Glass and Ceramic Research Institute, Calcutta (1950); Central Food Technological Research Institute, Mysore (1950); Central Drug Research Institute, Lucknow (1951); Central Road Research Institute, Delhi (1952); Central Electro-Chemical Research Institute, Karaikudi (1953); Central Leather Research Institute, Madras (1953); Central Building Research Institute, Roorkee (1953); Central Salt Research Station, Bhavnagar (October 1954); and the Central Electronics Engineering Research Institute, Pilani (1953). Not all these laboratories are fully working yet, as may be judged from the dates of opening.

This impressive record of work carried out or projected mainly during the past five years is followed by an account of the extensive investigations which have been or are being sponsored by the Board or the Council of Scientific and Industrial Research through its various research committees in such varied fields as scientific instruments, radio research, the ionosphere, high-altitude research, artificial rain, the measurement of geological time in India, gas turbines, the dyestuffs industry, biochemistry, malaria chemotherapy, pharmacology, the vanaspati industry, essential oils, plastics, and atomic research. Special committees have been appointed from time to time to deal with specific problems such as synthetic petrol, power alcohol from bagasse, research and development of gas turbine and jet propulsion engines in India, and low-cost housing.

Two chapters on the patent activities of the Council and the means taken to assist the utilization in industry of the results of the investigations it has sponsored and on the publications of the Council are followed by a brief note on the Indian National Scientific Documentation Centre, established at New Delhi in 1952 under the administrative control of the Director of the National Physical Laboratory. Besides some notes on the way in which the activities of the Council are financed and on its other activities, such as the co-operative research associations and the fellowships and scholarships instituted by the Council, the volume includes full lists of staff and of the personnel of the several boards and research committees, of research schemes, of patents and patent applications on behalf of the Council and of publications, including a classified bibliography of scientific and technical papers during 1940–53.

Simultaneously with this volume, the report of the Second Reviewing Committee*, constituted with Sir Alfred Egerton as chairman to report on the activities of the Council during the past five years, has been published; while the development of the Council's work has clearly been influenced by the experience of the Department of Scientific and Industrial Research in Great Britain, it is equally clear that there has been no slavish copying but that attempts have been made to shape both the organization and activities in accordance with Indian needs and conditions. The Reviewing Committee records the considered opinion that the twelve very fine modern laboratories which have been built are well sited and designed and have been well equipped at a very reasonable cost and that, except for certain important developments to which the Committee directs attention, they cover a range of research in science and industry which appears to be adequate for the next four years, although expenditure on research in India is far from being on the scale of highly industrialized countries, such as the United States or the United Kingdom. Recurrent grants to the Council from the Central Government have increased from 1,100,000 rupees in 1942–43 to 17,350,000 rupees in 1953–54, recurrent expenditure increasing from 695,611 rupees in 1942–43 to 12,928,765 rupees in 1952–53.

The policy of the Council in establishing these national laboratories and institutes has, in the Committee's opinion, been fully justified; the directors have been well chosen, the staffs are keen and are doing good work. The Reviewing Committee does not recommend any reorganization, but it makes some suggestions to improve the efficiency of operation and co-ordination. For example, the directors should be given as much freedom as possible in administration, with more time to exercise scientific guidance, the number of research committees—at present twenty-five—should be kept within bounds, and committees should be terminated when their work does not warrant two or three meetings a year, and further consideration of the relations between the national laboratories and institutes and the universities is recommended so as to ensure that the whole scientific organization operates in concert

---

* Council of Scientific and Industrial Research, India. A Review. Pp. 142. (New Delhi: Council of Scientific and Industrial Research, 1954.)

* Report of the Second Reviewing Committee of the Council of Scientific and Industrial Research. Pp. viii+98. (New Delhi: Council of Scientific and Industrial Research, 1954.)

There are sensible suggestions for co-operation in this field, including the interchange of facilities and of staff and welcoming the establishment of a University Grants Commission to provide grants for ensuring salary scales to attract staff of high quality, and the Committee stresses the importance of encouraging research at the universities and higher technological institutes Emphasizing equally the importance of co-operation with industry, it recommends that the liaison officer at the Council's headquarters should be responsible for furthering all such collaboration between the Council's institutes and laboratories and other research organizations Special attention is directed to the need for closer co-ordination and co-operation between the Council and the medical and agricultural research services, and more active co-operation with government departments is also recommended to facilitate utilization of the results of research carried out under the Council For the same purpose, as much help as possible should be given to the National Research Development Corporation, and the institutes should be assisted to establish pilot plants

The Reviewing Committee favours the establishment of further research associations where the size of an industry would justify this procedure, and it is obvious that, with regard to the utilization of research results, the dissemination of information, development and the formulation of research programmes, experience in India is not dissimilar from that in Britain The Committee's remarks as to the way in which the Council could give the measure of direction to the research done under its ægis necessary to ensure that it is related to India's needs and to the general advance of science are of considerable interest Ideas, it recognizes, must come mainly from the centres of research and, as research programmes, or less formally, they are discussed at meetings of the Council's research committees At this stage they should be related to the general plan for India and to the state of science and technology, and the Reviewing Committee suggests that the principal executive officer and director of the Council should be able to call together such members of the Advisory Board, directors and advisory committees of the laboratories and others from medical or agricultural research or the universities as would be needed to assess the importance and priority of particular ideas, and to suggest suitable laboratories within or without the organization where the research could be initiated He would thus be enabled to present to the Advisory Board of the Council a directive in relation to the programme which is submitted to the Board for review at least twice a year.

The developments which the Reviewing Committee considers desirable to complete the Council's cover of India's requirements are the Institute of Mining Research and the Central Mechanical Engineering Research Institute, both of which are to be established, the latter at Calcutta, mainly through private benefaction, and in this connexion the Committee comments on the need to attract young engineers to undertake research It has also been agreed to accommodate a Telecommunications Research Institute in the National Physical Laboratory, where the Defence Science Laboratory is also temporarily housed It recommends that full opportunities should be given for astronomical research in India, so as to utilize the ability for mathematical analysis and physical investigation for which Indian scientific workers are particularly noted, and that the Council should at least foster astronomical research in the universities and other centres The proposal to establish meteorological stations is welcomed and a centre for geophysical research is also recommended.

Provision for atomic energy is regarded as adequate, but some concentration of research effort on the utilization of solar energy, either direct or by chemical or biochemical means, is recommended, as well as further attention to the de-salination of water and concerted efforts to conserve, improve and recover the soils of India Physiological research requires full attention, and genetics also needs adequate cover. The Committee concludes its report with a tribute to the work already accomplished in so short a time and to the ability of the Council's chief executive officer, Sir Shanti Bhatnagar

DEEP-WATER MOVEMENTS IN THE OCEAN

MUCH less is known about water movements in the depths of the oceans than about surface currents The oceanic circulations, however, involve movements of water at all levels, with vertical as well as horizontal components, so that the movements in the various layers are to some extent dependent on one another Deep-water movements are therefore of interest to meteorologists as well as to marine physicists, biologists and geologists.

A Geophysical Discussion on this subject took place at a meeting of the Royal Astronomical Society on October 22 Dr G E R Deacon (National Institute of Oceanography), who was in the chair, referred to a quotation from Croll, towards the end of the past century, to the effect that the cause of ocean circulations was a question belonging to the domain of physics and mechanics, whereas few physicists or mathematicians of note had given much attention to it, this, he said, is no longer true The contributions to the Discussion, continued Dr Deacon, would show evidence of various ways in which problems of oceanic circulation are being tackled theoretically and by laboratory experiments as well as by observations in the oceans themselves

In the first paper, Prof K F. Bowden (University of Liverpool) gave a brief account of the main features of the oceanic circulation below the surface layers, as deduced from the observed distributions of temperature, salinity, oxygen content and other properties He referred to various estimates which have been made of the velocities of the deep-water movements, such as those based on the balance between horizontal flow and vertical or lateral mixing, and particularly to the charts of currents at 800 m. and 2,000 m. in the Atlantic Ocean deduced by Defant on the basis of the absolute dynamic topography Most estimates agree in order of magnitude, giving the velocity of flow of the Antarctic

The Study of Prehistory

J. G. D. CLARK

The inaugural lecture of the new Disney Professor of Archaeology at Cambridge. *2s. 6d. net*

Excavations at Star Carr

J. G. D. CLARK

A full account of the finds—'discoveries amongst the richest of their kind'—at an early Mesolithic site near Scarborough. In his last chapter Professor Clark sets Star Carr in the context of European prehistory. There are also chapters on lake-stratigraphy, pollen-analysis and vegetation by D. WALKER and H. GODWIN and on faunal remains by F. C. FRASER & J. E. KING. 24 plates, 80 figures *63s. net*

CAMBRIDGE UNIVERSITY PRESS

Industrial Dust

New Second Edition

PHILIP DRINKER

Professor of Industrial Hygiene, Harvard School of Public Health

THEODORE HATCH

Professor of Industrial Health Engineering, Graduate School of Public Health, University of Pittsburgh

Available shortly from your bookseller

McGraw-Hill London

The culmination of extensive practical application, this book is the work of authors who have been associated with the field in teaching, research and practical consulting work throughout their professional careers

It presents a critical presentation of dust control in relation to the health of workmen, analysing not only dust conditions but also methods of dust control, how clean the air should be and how to clean it

The new second edition contains rewritten matter, revision and additions, to such an extensive degree as to make it virtually a new book

The work is divided into three major sections

1. **The physical substances composing dust and fume suspensions, and their effects upon man ;**
2. **Analysis, measurement and microscopy of fine dust ;**
3. **The practical control of dust and the use of respiratory protective devices.**

New material includes a bibliography covering developments in the field since 1936, a description of the engineering methods which have contributed to the gradual control of silicosis, and a detailed presentation of dust respirators whose use has now been accepted as sound industrial practice. Completely new illustrations reflect the latest changes in methods and techniques

Relating their material to an over-all health scheme, the authors approach their subject comprehensively in its engineering, laboratory and medical aspects

9 × 6 inches 371 pages 71s 6d

Aspects of Deep-Sea Biology

N. B. MARSHALL, M.A.

An outline of life found in the deep oceans, and of the physical nature of the deep sea, and the ways in which this information is obtained. The drawings by the author's wife in black-and-white, and colour, make this one of the most beautifully illustrated scientific books to be produced for a long time 35*s.*

General Principles of Geology

J. F. KIRKALDY, D.Sc., F.G.S.

A new text-book for University students by the Head of the Geology Department of Queen Mary College, London Modern theory is adequately covered but practical and economic applications of geology from water supply to road-making are by no means overlooked 25*s.*

Man and Energy

Prof. A. R. UBBELOHDE, F.R.S.

"An entertaining and well illustrated account of the way in which the muscular energy of men and animals has been replaced for many purposes by energy from coal, oil, water power and nuclear fission The author brings to the subject a lucid style, a dry wit and an eye for the apt statistic that make the book a pleasure to read " *Times Educational Supplement.* 18*s*

The Gyroscope Applied

K. I. T. RICHARDSON, M.A.

"Intended for all who have heard the name gyroscope and would like to know exactly what it is, why it works and how it is used at sea and in the air " *The Nautical Magazine.* 30*s*

All the above books are fully illustrated

Hutchinson's Scientific and Technical Publications

New and forthcoming books

The Chemistry of Lipids of Biochemical Significance

J A LOVERN, D Sc, F.R I C

(Monographs on Biochemical Subjects)

This book presents in concise form an account of those aspects of lipid chemistry most likely to be of general interest to biochemists It is, however, sufficiently detailed and authoritative to be of almost equal value to the specialist in lipid chemistry

With 2 diagrams 8*s* 6*d*

The Nitrogen Metabolism of Micro-Organisms

B A FRY

Lecturer in Microbiology, University of Sheffield

(Monographs on Biochemical Subjects)

This monograph provides a convenient introduction to one important section of microbial biochemistry The underlying theme is none other than that known to all biologists as the 'Nitrogen Cycle,' and an attempt has been made to analyse some of the component steps of the cycle from the standpoint of the biochemistry of the various reactions and the micro-organisms concerned

With 3 plates and 15 diagrams 9*s* 6*d*

The Infra-Red Spectra of Complex Molecules

L J BELLAMY

Principal Scientific Officer, Ministry of Supply

'May well become the analytical handbook for those using IR techniques, and workers in the field owe a debt to both author and publisher for its production ' *British Bulletin of Spectroscopy* 35*s*

New edition

O G SUTTON, B.Sc, F R S

Director of the Meteorological Office

(Monographs on Physical Subjects)

With 4 diagrams 2nd edition revised 8*s* 6*d*

METHUEN

MACMILLAN BOOKS

Nuclear Species

H E HUNTLEY, B Sc, Ph D.

University College of the Gold Coast

Although this book is written primarily for the student working for university honours examinations in physics or chemistry, its lucid style should recommend it also to the general reader with scientific training or interests. In it the systematics of the nuclides, set out in order and examined in detail, lead to an up-to-date account of the stability valley of the isotopic chart, the "magic numbers," and other recent developments, including a section on the origin and age of the elements. 21*s.*

Introduction to Factor Analysis

BENJAMIN FRUCHTER

Associate Professor, Department of Educational Psychology, the University of Texas

A great increase in the use of factor-analytic procedures has taken place since the time when Charles Spearman first presented his theory and method of factor analysis This widespread application has created a need for a book such as this which keeps in mind the beginner, yet develops and presents the concepts of factor analysis in a logical order Theory, methods, and techniques are clearly presented by Professor Fruchter in a step-by-step fashion that will have special appeal to those without expert mathematical background, while numerous problems and their answers have been included 37*s* 6*d*

Freedom and Control in Modern Society

Edited by MORROE BERGER, Assistant Professor of Sociology, Princeton University,
THEODORE ABEL, Professor of Sociology, Hunter College,
CHARLES H. PAGE, Professor of Sociology, Smith College

This book was written in honour of Robert Morrison MacIver, one of the great thinkers in the fields of political philosophy and sociology In it scholars who have been his students or colleagues contribute a series of papers bearing on many aspects of the problem· "In a highly organized world how far can freedom go, how close must control be ?" Falling into three general categories—individual freedom in an age of large-scale organization, inter-group relations, and the relation of the individual to his government—some of the most perplexing and controversial topics of our time are illuminated. 45*s.*

Intermediate Chemistry

Sixth Edition

T M. LOWRY, C B E, M.A, D Sc, F.R.S

Late Professor of Chemistry in the University of Cambridge

A C CAVELL, M.A., B.Sc.,

Senior Science Master at Uppingham School

The main intention of this new edition of *Intermediate Chemistry* has been the re-writing of the Organic Section Several changes have been made to the Inorganic Section, and there have also been a number of other alterations to and extensions of the work, which is designed to provide a complete text-book of chemistry for Intermediate and General Certificate (Advanced and Scholarship) Examinations. 18*s.*

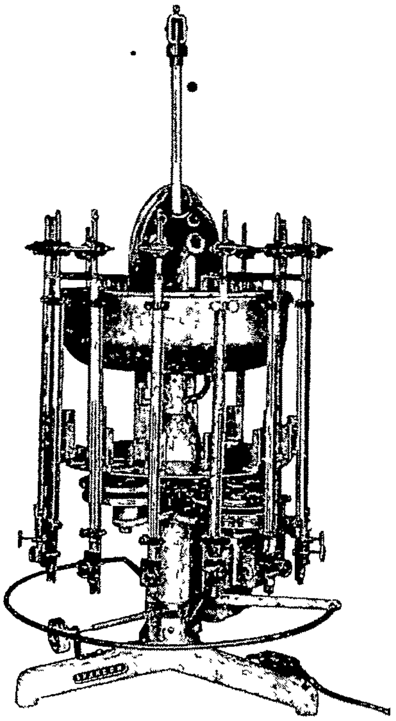
ROTARY WARBURG APPARATUS



MODEL VB/14

This is the most convenient apparatus for micro-respiration work, its circular shape makes for ease and speed of operation and for economy of space The unit is more compact than a rectangular bath of equal capacity, as it accommodates manometers round its entire periphery The whole apparatus can be rotated around its base, so that any particular manometer can be brought directly in front of the operator, and the apparatus can be installed in any position (in a corner if need be) since only one side need be accessible

The circular shape bath has proved ideal for maintaining a uniform temperature as there are no "dead spots" to hinder circulation Temperature is constant to within ± 0 01°C. Shaking speed and amplitude are adjustable, and provision has been made for secure and positive mounting of the manometers—no wobbling!

Post free in U.K.

D-698 WESTON STANDARD CELL

This new cell combines the robustness and small size of our D-550 Miniature Standard Cell with a high capacity previously only obtainable in larger and more expensive types such as our D-402.

Whether you require a standard of E.M.F. for an industrial application or for laboratory use, this new cell will meet your needs and give many years of reliable service.

SPECIFICATION

E.M.F.	$1.01859\text{V} + 110\mu\text{V} - 90\mu\text{V}$ at 20°C.
Temperature coefficient	-0.00004 per °C.
Discharge rate	Up to $20\mu\text{A}$ for short periods
Internal resistance	600 ohms
Overall dimensions	$1\frac{15}{16}''$ x $1''$ x $3\frac{3}{8}''$
Weight	4 oz.

Our D-550-A and D-402 Weston Standard Cells are still available

The case of *Agriotes obscurus* . . .

Wherever potatoes are grown, wireworms are pretty certain to be encountered and to damage the tubers. In the U.K., for example, this destructive pest populates the soil in some areas to the extent of over a million per acre. In heavy local infestations this figure is probably doubled. Damage fluctuates, but it is nothing unusual to find over half a crop unfit for the table.

With wireworms on the increase, British farmers have welcomed the arrival of aldrin. This year in the United Kingdom alone over 90,000 acres of potatoes will be protected, mostly with aldrinised fertilizer. This Shell insecticide is the most impressive destroyer yet discovered for pests in the soil—non-tainting and exceptionally suitable for compounding with fertilizer.

Just 2½ lbs. of aldrin per acre guards potatoes from wireworm and other soil pests right through the growing season.

Aldrin is fast becoming recognised as being the best of all soil insecticides. A little goes a long way and lasts a long time. Now in world wide use, aldrin gives full control of many pests previously difficult to 'get at' economically.

Another recently developed Shell insecticide is dieldrin *possessing exceptional persistence. On foliage,* dieldrin *controls a very wide range of weevils, beetles, flies and other crop-eating insects. It is also extensively used as a residual spray against disease-carrying insects.*

Have you a stubborn pest problem to be solved?

aldrin

aldrin and dieldrin are SHELL insecticides for world wide use

For further information apply to your Shell Company

UNDESIRABLE IN RESEARCH OR PRODUCTION

Both production and research operations often require rigidly controlled humidities to preserve materials, safeguard chemical analyses or simulate ultra-dry conditions. For these small-scale operations, the Birlec Lab Lectrodryer, delivering 100 cu. ft. hr., maintains dew-points down to minus 70°C. Both atmospheric and high pressure models are available. *The coupon below will bring you further information about Lectrodryers and a pocket-size data card, giving HUMIDITY TABLES from — 70°C. to 40°C: you will find both useful.*

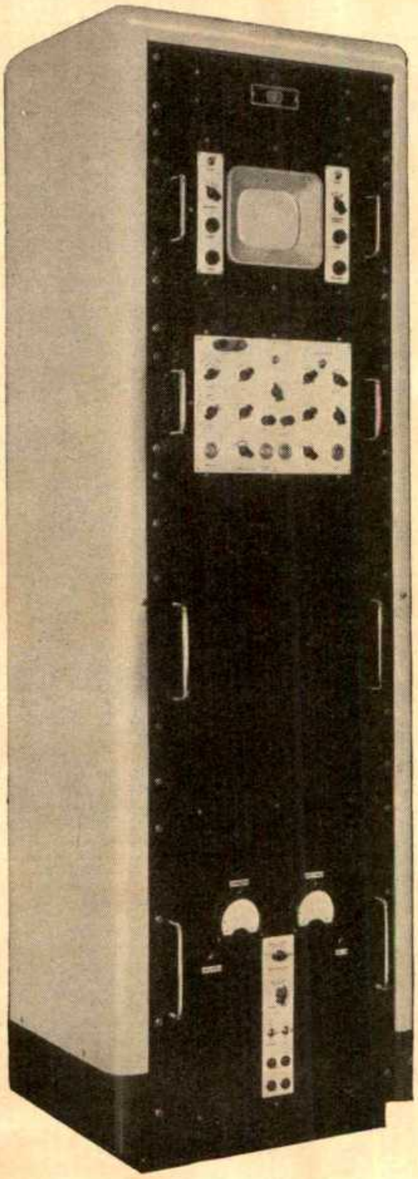
PROGRESS IN CONTROL



SUNVIC
PULSE HEIGHT
ANALYSER

An instrument for the analysis of a complex pulse amplitude spectrum into groups of known height according to their voltage amplitude.

It displays up to a maximum of 120 channels and can store 1,200 binary digits. The design is based on that of Hutchinson & Scarrott (*Phil. Mag.*, 42, 792, 1951) and the instrument is made under licence from the N.R.D.C.

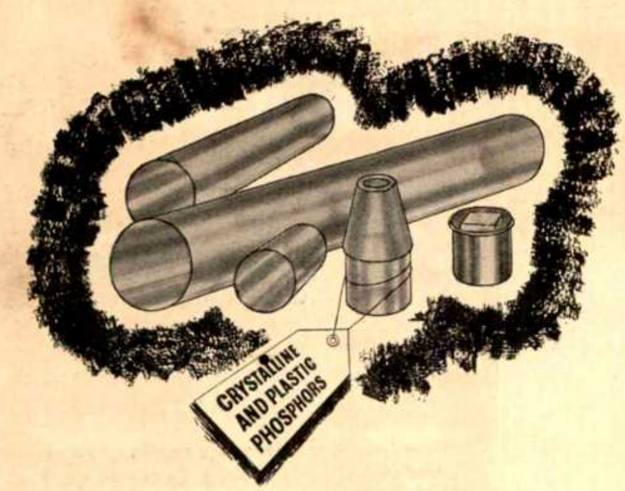
TAS/Sc.305



Scintillators

'PAMELON'

The NEW I.D.L. high activity plastic scintillator

High energy yield with fast decay time and good optical characteristics, ensures equivalent effectiveness to many crystalline phosphors.

Available in large bulk and sections suitable for Alpha, Beta and Gamma rays and X-rays. Easy to fabricate and polish. Stable at low temperatures and pressures.

Pamelon is one of our wide range of scintillators which includes SODIUM IODIDE CAPSULES, HORNYAK BUTTONS, ZINC AND CADMIUM SULPHIDE.

Bottom Water, for example, as about 1 cm./sec., so that it would take about twenty years to travel from the Antarctic to the Equator. Estimates by carbon-14 dating technique, however, have given a time as long as eighteen hundred years, while photographs of sand ripples have suggested currents greater than 15 cm./sec. at the bottom. The direct measurements which have been made to date have been in some cases in agreement and in others in disagreement with the estimates. The difficulties of using a current meter from an anchored ship lead to possible errors of measurement which may, in some cases, be comparable with the deep currents themselves. New methods and techniques, some examples of which were given by subsequent speakers, are needed in the study of deep currents.

The next two papers were of a theoretical character, and both were concerned with currents due directly or indirectly to the stress of the wind on the sea surface. Dr. E. T. Eady (Imperial College of Science and Technology, London) gave a critical account of recent theories of the wind-driven large-scale circulations, which have shown that the concentration of flow towards the western sides of the oceans arises as a consequence of the variation of the vertical component of the earth's rotation with latitude. The basis of such theories, as developed by Stommel and Munk, is the integrated vorticity equation, from which it may be inferred that, in a steady state and in the absence of stresses on the 'sides' of a vertical column of water due to turbulent motion, the mean north–south motion of the column is proportional to the external torque, presumably due almost entirely to wind stresses on the surface of the ocean. The reason is that the rate of (absolute) rotation of the column must be almost the same as the vertical component of the earth's rotation, and this increases with latitude. Since the external torque is mainly a function of latitude and all the water cannot move north or south, it is necessary to assume that short-range turbulent stresses play an important part in a narrow region on the western side of the ocean, where there is a strong narrow current in the opposite direction to the drift elsewhere. A difficulty in interpretation is that we do not know the mean currents, measurements of density gradient yielding only relative currents. As a step towards a more detailed theory, Dr. Eady showed that, if we suppose that the turbulent motion which transmits the surface stresses downwards is limited to a rather shallow layer, then there must be convergence in this layer near latitude 30° which forces down the light surface water. There are, however, difficulties in applying such a simple theory in low latitudes.

Dr. W. V. R. Malkus (Woods Hole Oceanographic Institution, U.S.A.) gave an account of a treatment representing an extension of work by H. Stommel, which was based on the assumption of a two-layer ocean, considering particularly its application to the Gulf Stream. The two layers, of different temperatures, and hence of different densities, are separated by an interface of variable depth which meets the surface in a line corresponding to the cold northern edge of the Gulf Stream. The surface layer is assumed to be in geostrophic balance and its vorticity conserved. Dr. Malkus gave a solution for the depth of the upper layer as a function of latitude and the transport by the current in the upper layer for a given distribution of wind stress. He suggested that momentum is lost from the Gulf Stream by eddies which break off from the meanders, the momentum being dissipated in the cold water to the north of the current and the heat lost by radiation and evaporation to the atmosphere. Assuming that half the momentum of the Gulf Stream is lost in this way, and taking the appropriate temperatures for the two layers, a reasonable solution may be obtained for the loss of heat energy and for the depth of the interface. For a transport corresponding to the wind stress curl as observed, the maximum depth is 800 m. Dr. Malkus suggested further that the water lost from the surface layer in this way returns as a deep current, with a velocity which would be about $\frac{1}{8}$ cm./sec. if distributed over 3,000 m. of depth. This might be re-incorporated in the surface layer in lower latitudes by the deepening of the thermocline by about 50 m., which occurs in the winter months.

Mr. T. V. Davies (King's College, London) dealt with a possible experimental approach on the model scale, referring to the 'dish pan' experiments of Fultz in Chicago and Hide in Cambridge, which were designed to study motions in the atmosphere on the rotating earth. In the experiments, a liquid is contained in the annular space between two concentric cylinders, which are rotated about their common axis. Heat is supplied at the outer boundary while the inner boundary is cooled, corresponding to the heating of the atmosphere in the equatorial region and cooling near the poles. The flow régime depends, other things being equal, on the angular velocity of rotation. For low rates of rotation, the water particles rise near the outer boundary, move inwards near the surface, sink near the inner boundary and flow outwards below in a uniform manner. This has been called the 'Hadley régime'. When the rate of rotation exceeds a critical value, another system of flow, known as the 'Rossby régime', sets in, in which the surface flow becomes concentrated into wave-like paths, similar to the 'jet streams' which occur in the upper atmosphere. Mr. Davies presented the theory on which these experiments are based, starting from the equations of motion, continuity and heat transfer, and arriving at three parameters governing the motion, by which the transformation from model to full-scale flow should be carried out. The values of these parameters for the ocean are of the order of a hundredth of those for the atmosphere, but they should be within the range readily attainable in experiments. The type of motion studied hitherto derives its energy from thermodynamic processes, which are predominant in the atmosphere. Mr. Davies pointed out that the surface stresses, which are important in the case of the oceans, have not been represented, but suggested that they might be included by using two layers of liquid in the experiments.

In the last contribution, Mr. J. Crease (National Institute of Oceanography) returned to full-scale observations in the ocean, describing some results obtained by three different methods during last May and June in R.R.S. *Discovery II*, working in an area between Spain and the Azores, about 42½° N., 20½° W., in a depth of about 4,000 m. In the first method, a deep drogue constructed of two steel frames 6 ft. square, in the form of a cross, and covered with canvas, was suspended by piano wire from a pair of small elliptical floats. Two such drogues, one at 1,000 m. and the other at 2,000 m., were tracked for several days, their positions being fixed by radar from the ship, relative to a marker buoy moored by piano wire to a sinker on the bottom. Both indicated a flow directed approximately towards the east-north-east, the drogue at 1,000 m. averaging about 0·2 knot (about 10 cm./sec.) and that at 2,000 m. about 0·1 knot. The second method consisted of taking normal hydrographic stations down to 3,000 m. at the four corners of a square of 10 miles side, and computing the velocity perpendicular to each side of the square relative to that at 3,000 m. The results indicated an apparent flow into the square across one pair of opposite sides and outwards across the other pair of sides. Mr. Crease suggested that this surprising result might be due to tidal changes in the slopes of the isobaric surfaces, the whole four stations having been occupied in a period of a little more than twelve hours. The third method employed a new technique, analogous to the use of an inverted radiosonde. A supersonic transmitter, emitting a 'ping' every few seconds, was attached to a type of parachute, so that it sank slowly through the water at a rate of about 250 m./hr. Its position was fixed at intervals by sound-ranging, the pings being received by four hydrophones, one suspended below the ship and the other three below sono-radio buoys, which were moored to the bottom by piano wire, and which transmitted the received signals to the ship. The relative positions of the buoys and the ship were fixed by radar. The results showed a current in the same direction as that indicated by the drogues, but of a greater magnitude: about 0·5 knot down to 1,200 m. and decreasing at greater depths.

The discussion which followed reflected the interest aroused in the new theoretical and experimental approaches. In reply to suggestions on the sinking transmitter technique, Mr. Crease said that the design of a transmitter which would remain for a long period at a constant depth was being considered. Reference was made to the rotating model experiments of Von Arx at Woods Hole, Massachusetts, in which a basin of paraboloidal shape is used, providing for the variation of Coriolis parameter with latitude, and boundaries having the outlines of the actual ocean boundaries in the northern hemisphere are inserted. Air streams over the model simulate the atmospheric wind systems, so that these experiments are a study of the wind-driven ocean circulation and in a sense are complementary to the 'dish pan' experiments, which have been concerned with circulations arising from processes of heating and cooling. While much remains to be learned about deep-water movements and the part they play in the general oceanic circulation, it is clear that the subject is being attacked vigorously from several angles and that encouraging progress is being made.

K. F. BOWDEN

LABORATORY ANIMALS IN THE UNITED STATES

"THE need for adequate standards and methods in the procurement of biological materials for research, assaying, testing and teaching"—to quote Dr. Orson N. Eaton—has been recognized for many years. The biological materials referred to are laboratory animals, and the need has, since the Second World War, become pressing in nearly every country in the world. The first action on a national scale was taken by the British Medical Research Council, which set up the Laboratory Animals Bureau in 1947. Five years later, in 1952, the Division of Biology and Agriculture of the American National Research Council, in consultation with government, university and industrial representatives, created an Institute of Animal Resources, and appointed Dr. Eaton as its executive secretary.

This was not the first American organization to make its main purpose the study of problems connected with laboratory animals. In 1950 a private and voluntary group of veterinarians and others interested in the provision and use of animals for scientific work formed an Animal Care Panel. This Panel has met every year from 1950 onwards for the purpose of receiving communications from its members, and these communications, together with the inevitable and stimulating discussions, are reproduced as proceedings. The proceedings are circulated only to members of the Panel, which is unfortunate, for much of their contents deserves wider publication; but the financial resources of the group are limited, and wider publication would presumably be beyond them.

There was a need, therefore, for the Institute of Animal Resources, with its official backing, both moral and material, and the choice of a distinguished geneticist as its executive secretary was a good one. All problems relating to laboratory animals are not genetical, and the Board of the Institute represents many other interests; but as the work of the Institute progresses, genetics will become increasingly important, and it is well that such developments can be expertly anticipated.

The work of the Institute is complementary to that of the Animal Care Panel, and since one finds that many names on the Board of one are among the membership of the other, close collaboration between the two can be assured. In addition to Dr. Eaton as executive secretary, the membership of the Executive Board of the Institute is made up as follows: P. B. Armstrong, Marine Biological Laboratory, Woods Hole; N. R. Brewer, Central Animal Quarters, University of Chicago; T. C. Byerly, U.S. Department of Agriculture; G. B. Coursen, General Biological Supply House, Chicago; A. E. Earl, Ciba Pharmaceutical Products; H. G. Herrlein, Rockland Farms; G. E. Jay, jun., National Institutes of Health; D. Jenkins, Chemical Corps Biological Laboratories; G. W. Kidder, Amherst College; C. G. King, Nutrition Foundation; W. Landauer, University of Connecticut; C. C. Little, Jackson Memorial Laboratory; R. C. Percival, Lederle Laboratories; and C. A. Slanetz, College of Physicians and Surgeons, Columbia University.

The aims of the Institute are: (1) to survey and list existing sources of animal stocks used in biological (including agricultural, medical and industrial) research, testing and assaying; and to determine the consumers and the volume of demand for such material; (2) to perpetuate this activity by taking periodic inventories and keeping a live master registry of those sources, for distribution to all interested persons and groups of consumers (for example, research laboratories, academic institutions, government agencies, industrial and trade establishments, etc.); (3) to promulgate scientific standards of definition, terminology and tolerated variability in regard to genetic constitution, nutrition, freedom from disease, housing conditions and maintenance for the major groups of animals in use; (4) to act as a liaison centre on information regarding the detection, preservation and perpetuation of new or old strains of special importance for specific problems (for example, cancer); (5) to devise measures for ensuring adequate supplies of needed animal stocks in states of emergency (war, epidemics, etc.); and (6) to assist in the organization and facilitation of the international exchange of needed animal stocks.

The first publication of the Institute is a "Handbook of Laboratory Animals"[*]. This handbook has a page on genetics, by Dr. George E. Jay, jun.; a page and a half on nutrition, by Dr. Charles A. Slanetz; a page on diseases of laboratory animals, by Dr. N. R. Brewer, followed by twelve pages summarizing the more common infections of a wide variety of species; an extensive table of sources of animal supply; three pages on the uses of laboratory animals, with an extensive bibliography of uses; a short selection of general references; a table of users of laboratory animals; and a brief note on the importance and desirability of international exchange, both of information and of strains of animals of particular interest, which we in Great Britain can whole-heartedly endorse.

The main part of the handbook is occupied by the two tables, which have been compiled from the answers to questionnaires sent out by the Institute. The table of sources of animal supply is subdivided by species, and covers mice, rats, guinea pigs, rabbits, hamsters, dogs, monkeys, chicks and a wide variety of miscellaneous animals. There are columns showing strain, original source, breeding system, description, diet, disease control measures, uses and productive output, against each source of supply, which includes both laboratories and commercial breeders and suppliers. Although this list is far from complete for the country as a whole, and probably represents only a minority of total sources, it is formidable, and will undoubtedly be an immensely useful catalogue for any scientific worker wishing to select the most suitable animals for his researches. The tabulation is clear, and most of the information essentially useful. (A counterpart of this table is the "Laboratory Animals Bureau Catalogue of Uniform Strains maintained in Great Britain".) Further additions to the table have been promised, and any approach towards comprehensiveness will certainly enhance its value.

The list of uses of laboratory animals is certainly very incomplete, but, taken in conjunction with the table of sources, is a worth-while guide. Its expansion in subsequent issues would make it a useful reference index.

The second table, listing users of laboratory animals, contains information essential to the functioning of the Institute, but it is harder to see what interest it can have for others. Had it been necessary to show that the Institute was in fact well occupied, its inclusion in the handbook might have been justified, but the rest of the handbook is already sufficient evidence.

Such criticism of the Institute's work may appear ungenerous, but this would be a false impression. The Institute has undertaken a task, both of urgent necessity and of a complexity incomparably greater than in Great Britain, where the numbers of laboratories, of scientific workers and of animals used are so much smaller. It has tackled the problem with the vigour to be expected of our American colleagues, and the handbook, produced within two years of the establishment of the Institute, is ample tribute to its competence and industry. Only one who has faced similar tasks elsewhere can appreciate how much thought and work went into this enterprise, and we look forward with eagerness and confidence to further publications from the same source.

---

PROFESSIONAL STATUS OF MANAGEMENT

A WELL-KNOWN management consultant, Colonel L. Urwick, discusses in a small booklet[*] the question as to whether management is or is not regarded as a profession, and puts forward the view that the problem is not wholly academic or a matter of words. It can have considerable influence on such questions as whether or not during the next few years Britain will be able to pay its debts or must face a falling standard of life for its people. All that is necessary to establish the claim of management to professional status is to prove that it involves some branch of learning; in other words, that there is a body of knowledge bearing on the activity of management which can be taught and learned. In 1951 there were nearly seven hundred educational institutions in the United States awarding degrees at university standard in management subjects; the number of university students 'majoring' in this field was more than 370,000, and just over eighty thousand degrees were awarded.

In Great Britain the figures were proportionately much smaller; but a number of universities have degree courses in management. An intermediate examination in management subjects has been established, and it is national policy that technical colleges should provide facilities for those who wish to prepare for it. If there is no body of knowledge bearing on management which can be taught and learned, all these activities are meaningless. On what then, asks Colonel Urwick, is the resistance to this conclusion among certain business men founded? The suggestion that management is becoming professionalized seems to many 'practical business men' to threaten with the 'theorizing' that they so much dislike the very area which they had previously regarded as the special citadel of practicality. Secondly, many men in responsible positions to-day are wholly innocent of any formal preparation for their tasks. They have learned the technique and customs of their particular trade or industry by 'experience'.

It is always difficult for the individual to resist the conclusion that the process which launched his peculiar abilities upon the community was wisely conceived. The tendency to become *laudator temporis acti* and exaggerated loyalty to 'the old school' have similar roots in the eternal fidelity of human nature to itself. The very suggestion of new and improved methods of training which will systematize and shorten the acquisition of experience seems to many a direct threat to their personal integrity.

Others again are concerned lest, if young men who have not yet won their spurs are allowed to study the art of management, they will become overimpressed with their own theoretical knowledge. There is some truth in this. Most young men under twenty-five who have had the benefit of a higher education pass through a period when they overestimate the force of logical argument and underestimate the mutability of things It is a condition which the older men of wisdom learn to recognize and to correct with kindly tolerance.

---

[*] Is Management a Profession? By L. Urwick. Pp. 27. (London: Urwick, Orr and Partners, Ltd., 1954.)

Another traditional attitude which plays a part in this picture, curiously at variance with our preference for the 'practical', is the British prejudice in favour of amateurishness In business, being a director is still, in part, a stronghold of the amateur Many men are made directors of companies who have neither worked their way up through the ranks of management nor have qualified themselves professionally in other ways. They often represent important financial interests, which should be represented, but have no knowledge of the art and science of management or of the technique of the particular industry or trade with which the company is concerned To suggest to men who have absorbed this national prejudice in favour of amateurishness that business management should be treated as a profession seems deeply shocking

There are certain historical reasons why the title 'director' in business has become one of the last bastions of this crumbling edifice of social prejudice It is no accident that the highest class in the British Civil Service, that into which university graduates are recruited direct and from which the majority of the highest posts are filled, is known as the Administrative Class The second grade, recruited from secondary-school students, is termed the Executive Class Executive work—that is, management—commands far less social prestige in Great Britain than in the United States, where the greatest elective office in the world, the presidency, is by definition an executive office

The proposition that management should be treated as a profession cuts across many of these quasi-understandings and habitual ways of thinking, some of them with their roots deep in British history It means recognizing the employee, the salaried man with managerial duties, as much less sharply distinguished from the director than has been the case in the past.

Finally, in this order of objections, comes fear In recent years the leaders of business in Great Britain have had an uneasy time The Second World War exposed them to an orgy of government regulation from which they have not yet entirely escaped Men who have been thus harried are bound to be sensitive beyond the normal, to feel that any suggestion that their salaried employees are going to act together—and professional status does connote some form of professional organization which might, however improbably, issue in bargaining conditions—should be resisted at all costs

The objections to regarding management as a profession are all of them subjective They are fears, feelings, folk-ways, customary attitudes, prejudices in favour of, or against, this or that, and the best way to deal with a non-logical impulse or habit of thought which cannot be defended by argument—and any argument in favour of social distinctions is deeply out of sympathy with the spirit of the time—is to ignore it, to push it away below the threshold of consciousness Yet, assuming that the word management is used of the activity normally understood by the word and confined strictly to executive functions, there seems to be no insuperable practical obstacle to the professional organization of those engaged in this occupation

WELDING IN SHIP CONSTRUCTION

During the Second World War a large number of merchant ships were built in the United States, at a rate of production which could only have been achieved with the extensive use of welding In the circumstances, it is not surprising that a proportion of these ships should have suffered structural failure when in service It is now clear that most of the failures were examples of notch brittle fracture, such as has been experienced from time to time in many types of steel structure, both riveted and welded, on land and at sea, ever since iron and steel have been in common use At the time, however, it was widely believed that the welded ships were intrinsically more prone to fracture than their riveted counterparts With a different pattern of production, the British shipbuilding industry was not at that time faced with a similar problem In spite of this, the Admiralty Ship Welding Committee was set up in 1943 with terms of reference, "To consider and investigate special problems arising from the employment of welding in ship's structures and to advise on methods for their solution" This Committee has just been disbanded, and its last report has been issued[*]

Much of the work of the Committee was devoted to metallurgical studies relating to notch brittle fracture, and it is in this direction that the most radical changes have been proposed. Nevertheless, it was necessary to distinguish the differences in structural behaviour, if any should exist, between riveted and welded ships of otherwise identical design The series of trials carried out for this purpose deserve wide recognition for their excellence of planning and execution. Four ships were chosen for the major trials Of these, two were 12,000-ton tankers and two were 10,000-ton dry-cargo ships. The ships of each pair were identical, except for the alternatives of welded and riveted joints In addition to the more obvious differences of design between the tankers and the dry-cargo ships, the former had a preponderance of shell framing in the longitudinal, and the latter in the transverse direction. Although the primary object of the tests was to compare the stress distributions to which the riveted and welded ships would be subjected at sea, it was decided that this could not be undertaken directly. Alternatively, on one only, the welded dry-cargo ship *Ocean Vulcan*, an extensive investigation was made, not only of the forces which North Atlantic sea conditions produced, but also of the stresses and deflexions which similar forces produced when applied in still water by means of ballast loadings The latter were chosen to simulate various vertical and horizontal bending-moment conditions, shear forces and torsion moments The still-water investigations were also carried out for each of the remaining ships

[*] Admiralty Ship Welding Committee Report No R 6 Structural Tests in Still Water on Welded Dry Cargo Ship *Ocean Vulcan* Pp x+50+25 plates+109 diagrams+8 tables 30*s* net Report No R 7 Structural Tests in Still Water on Riveted Dry Cargo Ship *Clan Alpine* Pp x+18+16 plates+116 diagrams+9 tables 30*s* net Report No R 8 S S *Ocean Vulcan* Sea Trials—The Forces Acting on the Ship at Sea Pp viii+175+17 plates 35*s* net Report No R 9 *Ocean Vulcan* Sea Trials—Detailed Analysis of Record No 1 E 3 (Loaded Condition) Pp viii + 17 + 87 diagrams 25*s* net Report No R 10 *Ocean Vulcan* Sea Trials—Detailed Analysis of Record No 6 E 7 (Loaded Condition) Pp viii+200 (187 pages of diagrams) 42*s* net Report No R 11 S S *Ocean Vulcan* Sea Trials Detailed Analysis of Record No 6 W 5 (Ballast Condition) Pp viii+12+124 diagrams 27*s* 6*d* net Report No R 12 Structural Trials on S S *Ocean Vulcan* and S S *Clan Alpine* Discussion of Results (In the press) (London H M Stationery Office, 1953 and 1954)

The confidence with which the results of such investigations may be accepted rests clearly on the independent checks which may be made on each set of readings. In this respect the investigators were particularly successful. In the static trials, close comparisons were possible between measured and calculated stress distributions at the test sections and between measured and calculated deflexions. In the sea trials similar successful comparisons were possible between stress distributions measured at a hull cross-section and those predicted from the forces estimated from water-pressure distributions on the submerged portion of the hull, together with hull acceleration measurements.

In general, none of the results does other than confirm the methods now adopted for calculating necessary hull structural strengths, and dispose of the possibility that any broad difference exists between the structural characteristics of otherwise similar welded and riveted hulls. Nevertheless, many differences of detail are exposed. It is shown, for example, that the shrinkages which take place when welds are deposited along plate edges give rise to initial buckles considerably greater than where riveting is employed, so that bending stresses are increased. Under these conditions, longitudinal framing is particularly effective, since the supporting members are disposed more favourably for the suppression of buckling due to longitudinal compressive loads. It is perhaps unfortunate that this is not stated among the conclusions, although the evidence is clearly given. On the other hand, one may wonder why so much space is devoted to proving that rivet slip is not important in contributing to the deformation under load of riveted hulls.

Some idea of the immensity of the task of computation from the measurements may be grasped by reference to the number of tables and diagrams in the various reports, and it is scarcely surprising that several years elapsed before publication was possible. It is fitting tribute to those concerned in the work that the results may now be so readily assimilated by the reader. A. A. Wells

NEW ZEALAND DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

REPORT FOR THE YEAR 1953–54

THE twenty-eighth annual report of the Department of Scientific and Industrial Research, New Zealand*, covers the year ended March 31, 1954. Besides the Minister's statement and the Secretary's report, it includes brief, but not technical, reports from the several branches of the Department and the incorporated research associations, and from the Cawthron Institute and the university colleges to which grants were made by the Department; to most of these latter reports a list of publications is appended. The new building for the Grasslands Division at Palmerston North, which is nearing completion, should largely meet the needs of this Division, and new accommodation has been provided at Lower Hutt for three research associations, while the Botany Division is now to be transferred from Wellington to a suitable building at Christchurch. In future, branches of the Department will publish periodic reviews of their work, giving more detail than was possible in those previously included in the Department's annual report; those in the present report merely list the principal projects under way.

The Secretary's report stresses the need for adequate and fireproof accommodation for the Botany Division and Geological Survey; but the additional land acquired at Owairaka should suffice for the needs of the Plant Diseases Division and the Fruit Research Station for many years to come. The Department's activities in oceanography have been reorganized, and increasing attention will be given to marine biology and geology and to studies of the temperature, salinity and movement of water masses in the New Zealand area. Net expenditure of the Department was £1,025,414, compared with £941,723 during 1952–53, and the staff at March 31, 1954, was 937, compared with 931 on April 1, 1953. Only six of forty-two vacancies for which provision was made in the estimates were filled during the year, and the professional staff was unchanged at 374; technical staff numbered 347. Of the total expenditure, 24·7 per cent was for services to other government departments and public bodies, 53 per cent for services (including research) to farming and industry, 9·5 per cent for grants to research associations, university colleges, etc., and 12·8 per cent for administration, information services, and publications. It is also estimated that about 47 per cent of the expenditure is on research and service to farming industries.

In view of the elimination of the technical reports from the various branches previously included, the Secretary's report gives a rather fuller general survey than previous reports. During the year the Soil Bureau published as a bulletin a "General Survey of the Soils of North Island, New Zealand", and preparatory work for the issue of a similar publication for South Island has commenced. A survey has also been commenced of the minor-element status of the major soil types in the Dominion, using sweet vernal grass, which grows throughout New Zealand, to indicate the soil nutrients available to it and thus eliminate the uncertainty of chemical methods of extraction of soils. The extensive investigation of bloat of dairy cows, which was commenced in 1952, indicates to date that bloat is caused by some soluble material or materials with foam-producing properties, and that a study of the physical condition of the rumen contents is the most promising line of investigation. A new strain of cocksfoot, based on plants of New Zealand origin, has now been produced and released under certification after trials which indicate an annual production 18–20 per cent higher than that of *C23*. The new strain has a wider seasonal range of production and begins growth earlier in the spring.

Trials carried out by the Plant Diseases Division in widely separated areas have shown that the establishment of red, white and subterranean clovers can be markedly improved by inoculating the seed with selected efficient strains of nodule bacteria, and an economic but effective method of applying the inoculum to commercial quantities of seed is being sought. The use of commercial insecticide–fertilizer mixtures for the control of grass-grub and *Oxycanus* in pastures by methods worked out by the Entomological Research Station continues to increase during 1952–53, 4,467 tons was used for this purpose compared with 2,109 during 1951–52, and production of DDT-superphosphate during 1953–54 is estimated at 6,200 tons Of about 150 tons of DDT used in the Dominion, 107 tons is used to control these two pests alone, about 20 tons being used for orchard work and 20 tons for fly sprays and other purposes In the Canterbury and Waikato areas alone, grass-grub attack on the 3 5 million acres of pasture is liable to cause an annual loss of £4 million. Attention is being given to particle size, wettability and the distribution of insecticide within a batch of fertilizer The Entomological Research Station's investigation into the roles of *Eriococcus* and the associated fungus in relation to the death of manuka (*Leptospermum scoparium*) continued and also the mapping of the distribution of *Eriococcus*

* New Zealand Department of Scientific and Industrial Research. Twenty-eighth Annual Report. Pp. 68. (Wellington Government Printer, 1954.)

Tests of introduced varieties of linseed indicate that Marine, although not yielding as heavily as Golden Viking in a disease-free year, is a more reliable variety for New Zealand owing to its resistance to fungus (Pasmo) and to rust disease, except the rare and weak Race 12 of rust. Steps are being taken to reduce the great variation of type within strains and varieties of commercial vegetable seeds, especially among the Brassicas, by bulk seeding of selected plants, followed by progeny testing and further selection, and lines of savoy cabbage have been developed and characterized by increased percentage of marketable heads and uniformity of type and maturity. A comprehensive bulletin covering present knowledge of plant virus disease in New Zealand, and describing the control of cherry plum mosaic among cuttings grown as stocks, which has been achieved by removing infected plants, was published during the year

Considerable progress was made by the Animal Ecology Section during the year with its analysis of data on reproduction and parasites of rabbits and with other rabbit population studies

The Geophysics Division is conducting a gravity survey which will provide information on the depth of volcanic debris overlaying the basement greywacke and also more detailed surveys of the Waiotapu area, using seismic and gravity methods to elucidate the geological structure, and magnetic and electrical methods to delineate the high-temperature conditions near the surface These surveys will provide the data required for the development of power from geothermal steam, and the Dominion Laboratory has continued and extended observations of the temperature and discharge of hot springs, the periods of geysers, etc Officers from this Laboratory and the Dominion Physical Laboratory have developed the technique of radiocarbon dating of carbonaceous materials for use in New Zealand, and a number of the ash showers blanketing a large part of the centre of the North Island have already been dated

In the Dominion Laboratory a small team has developed a process of drying meat in slices up to half an inch thick, in which the slices of frozen meat are submerged in melted fat at 140–160° F (60–71 1° C) and the moisture extracted under vacuum Satisfactory material has been obtained from both beef and mutton in pilot-plant trials and were tested by Sir Edmund Hillary on his recent Himalayan expedition. Flour testing and reporting procedures at the Wheat Research Institute have been improved, and experimental studies of baking processes continued Large reserves of coal in the Maramarua area for possible steam-electric generation were proved by the Geological Survey in co-operation with the Mines Department The Department is now responsible for the annual preparation of charts showing the magnetic variation of the compass for an extensive area of the south-west Pacific, and the shipping companies and Royal New Zealand Navy are co-operating in a programme to determine the chart error at about thirty selected points. Large-scale tests of promising pozzolanic materials for constructional purposes have been made at the Dominion Physical Laboratory Some eighty per cent of the original recommended range of standards equipment has now been received, including a Diesselhorst thermo-electric free potentiometer for temperature measurement and the first of a range of precision balances for calibrating weights, and an electron microscope which is in constant use. Full-scale field trials by the Extension Division of the Department of Agriculture indicate that the process for the production of fused calcium–magnesium phosphate from New Zealand olivine rocks, developed by the Chemical Engineering Section of the Dominion Laboratory, is technically feasible

POLITICAL SCIENCE AS A UNIVERSITY SUBJECT

A REPORT on "The University Teaching of Social Sciences Political Science"* has been prepared by Prof William A Robson on behalf of the International Political Science Association and published by the United Nations Educational, Scientific and Cultural Organization. Political science, writes Prof. Robson, "is, no doubt, the master science which can do most to assuage the maladies and struggles and conflicts of man in society", this is so, he argues, because "political science is concerned with the study of power in society"—a "fundamental concept" which "integrates all the various branches of the subject" Having regard, then, to the troubles of the world in which we live and the "burning practical importance" of political science, it might be expected that a large measure of attention would be paid both to teaching and to research in the subject, but the interesting and painstaking survey of developments in this field which Prof Robson has carried out shows that this is far from the fact His assumptions about the nature of political science being what they are, this leaves him with an interesting problem to solve

What Prof Robson has to say is illuminating, but somewhat pessimistic Political science exists as an under-developed territory, or backward area, within the universities of the Western world because it has never cut itself adrift from other subjects, such as law, economics and philosophy It is treated as a somewhat unwanted step-child, whereas, he asserts, it should be accepted as "a separate and clearly distinguished discipline" to which the same status should be accorded as any other of the basic subjects that form part of the university curriculum of a liberal education It is simply because those who have been responsible for making university and public policy have failed to recognize the importance of teaching and research in political science, Prof

Robson suggests, that the present somewhat lamentable state of affairs has arisen

On the other hand, it may be asked what have political scientists done to establish themselves in the influential position which Prof. Robson has marked out for them Is theirs, in fact, a 'master science' ? Here Prof Robson injects into the discussion some very wise remarks, which place the problem of the under-development of political science in a somewhat different setting It is evident to him that, in the light of our present knowledge, it is beyond the power of political science "to formulate general laws which associate in a precise manner particular causes with specified effects". The political scientist is, indeed, "dealing with a realm of thought and action about which men and women hold the most profound differences of opinion and belief" His methods are imprecise, and his work is apt to be influenced too directly by the winds of passion If this is accepted as the truth, where, it must be asked, do political scientists stand in relation to the other social and natural sciences ?

The bold claim that political science can exist as a 'master science' must indeed be relinquished in favour of something more humble. The solving of such problems as the 'cold war', the international control of atomic energy, race relations in Africa, the stimulation of "genuine citizen participation in government", and the protection of the world against "stiff-necked bureaucracies incompatible with democracy", which Prof Robson regards as the concern of the political scientist, is a task that will require the collaboration of all social scientists—supposing that they do not prove to be too much for the wit of man altogether. If political science is to flourish it must, in present circumstances, accept more help from the other social sciences than it contributes to them

We thus find ourselves in the position of seeking the foundations of a political science that can be taught as part of a liberal education. It may be suggested that it is because this has not been done with sufficient intellectual courage that the subject has failed to expand with the rapidity that the necessities of our times would appear to demand The solving of the political problems that are so essentially bound up with the acquisition and exercise of power within any society can only be achieved on an empirical basis, it is only in this way that we shall be able to lay the foundations of a subject of study which can be called truly scientific

In Great Britain we are in an especially favourable position to attempt this, because our tradition in political science has always been empirical or practical as well as philosophical or theoretical. We have never taken a sentimental or idealized view of the personalities or behaviour of our rulers As William Pitt remarked at the end of the eighteenth century, "unlimited power is apt to corrupt the minds of those who possess it", and we have acted accordingly It was in Prof Robson's own London School of Economics that Graham Wallas made such strenuous efforts to apply practical wisdom of this kind to the conditions of his own day, and it is for the contemporary political scientist, in collaboration with sociologists, anthropologists and psychologists, to work out a theory dealing with the use of political power which can be applied both to problems of government and administration, on one hand, and to those of the individual politician, administrator and citizen on the other T. S SIMEY

EFFECTS OF RADIATION AND OTHER DELETERIOUS AGENTS ON EMBRYONIC DEVELOPMENT

THE Biology Division of the United States Atomic Energy Commission sponsored a symposium on the effects of radiation and other deleterious agents on embryonic development, which was held on April 20, 1953, at the Oak Ridge National Laboratory, Tennessee The proceedings have been published as a supplement to the *Journal of Cellular and Comparative Physiology* (43, Supp 1, May 1954 Pp 337+6 plates, from the Wistar Institute of Anatomy and Biology, Philadelphia, n p). This symposium volume contains eleven full-length papers and some short but valuable summarizing remarks by Dr Paul Weiss. Each of the papers is followed by a discussion by the author and members of an obviously interested and critical audience

Four of the papers deal with the effects of ionizing radiations on developing embryos of the rat, an amphibian and the mouse, and one may perhaps add to this group a study on the outcome of pregnancy in women exposed to the atomic bomb blast in Nagasaki Experimental papers in this group have been mainly concerned to plot out the different types of radiation damage which follow exposure to irradiation at different times of embryonic development. The facts which are revealed are interesting and probably of considerable technological importance in a world in which ionizing radiation seems likely to become one of the normal hazards not only of war but also of peaceful industry. The interpretation which should be put on them still remains rather obscure Much of the discussion is in terms of critical periods, but, as Weiss points out, one is not justified in assuming that the crucial activities which bring about the final visible effects are produced at the actual time at which the irradiation is given, a situation which makes the identification of the critical periods by no means easy Moreover, the evidence suggests that radiation may produce many different types of damage, not only on the chromosomes but also on the cytoplasm

One might hope, perhaps, to have rather more understanding of the kind of damage produced by certain chemical substances such as the nitrogen mustards, the vitamins, cortisone, etc There are five papers dealing with such topics Again, the reader is confronted with a large amount of actual information, the explanation of which remains for the most part still to seek. Perhaps the most interesting of this group of papers is a further report by Landauer of the recent progress of his massive and thorough study of the production of phenocopies by chemical means in chick embryos In general, however, one gets the impression that our understanding of embryonic development would be better advanced by studies which employ agents the activities of which are more precisely understood than those of irradiation or toxic substances such as the mustards (for example, specific enzyme poisons or metabolic analogues), while for the interpretation of the embryonic effects of these 'blunderbuss' deleterious agents one will probably have to wait until studies on simpler systems have revealed more precisely the nature of the effects which they produce

Chromosomes of Monkeys and Men

CHROMOSOME numbers have been recorded in very few species of primates All observations have been on the male, the heterozygous sex The following are the more serious references

OLD WORLD PRIMATES			
Homo sapiens	European and Negro	48	Painter[1], Koller[2], La Cour[3], Hsu[4]
	Japanese	47	Oguma[5]
Pan calvus	Chimpanzee	c 48	Yeager *et al* [6]
Macacus mulatta	Rhesus macaque	48	Painter[7]
NEW WORLD MONKEY			
Cebus sp	Capuchin monkey	54	Painter[7]

Recent developments of technique, however, enable us to count the numbers and describe the forms of mammalian chromosomes with the same ease and accuracy as has long been possible for grasshoppers and newts We have therefore examined all the species of primates available to us The following are our counts (Figs 1–4)

Homo sapiens	
European, bone marrow (Fig 1) Indian testis	48
Papio papio, Guinea baboon, testis (Fig 2) *Macacus nemestrina*, pigtailed monkey, testis (Fig 3) *Macacus mulatta*, Rhesus macaque, testis (Fig 4)	42

The chromosomes of man and monkeys are generally not unlike In the spermatogonia illustrated they are, of course, more contracted than in the pre-myelocytes of the bone marrow With regard to the individual chromosomes we agree with Koller (who has studied meiosis), and with La Cour and Hsu, that in man X is a medium-sized chromosome and Y one of the smallest, although not individually recognizable at mitosis

The three species of monkey are alike in two respects in which they differ from man First, they lack the pair with median centromeres which is the largest pair in the human complement. Secondly, they have a Y chromosome which is much smaller than the human Y It is also much smaller than any other chromosome in their own complements and is therefore at once and always recognizable at mitosis (Figs. 2–4)

Since almost the whole of the Y in man can be accounted a pairing segment exchangeable between X and Y, all three monkeys must have a much shorter length of X–Y exchangeable genes than man The difference between man and monkey should show at meiosis, of which an account will be published later The similarity between the monkeys, on the other hand, should be seen in their capacity for hybridization. A cross has in fact been made between *Papio sphinx* ♀ and *Macacus mulatta* ♂, and offspring have been raised in captivity

These observations indicate that, apart from Painter's study of man, the earlier accounts based on sectioned material are not to be relied upon. They especially lead us to reject Oguma's claim of an unpaired X chromosome in the human male The Y chromosome is obvious and characteristic in all our four species as it has been in all other mammals studied Its absence, which would require an innovation in the centromere of the unpaired X, has never been established in any vertebrate

Finally, our observations show, what has not so far been clear, that chromosome form and number are unstable in the primates Both sex chromosomes and autosomes can be used to test relationships of descent. With this regard we should like to repeat the opinion[8] that the chromosomes of the great apes should be studied before these species die out altogether In order to facilitate this we must mention that our technique is a slight modification of that described by Sachs[9,10] Anyone who is able to obtain fresh monkey testis material should fix it in fresh 1 3 acetic alcohol and keep it, after twelve hours, at 0° C. Feulgen squash preparations should, however, be made as soon as possible (after twelve hours) Fixations may be sent by airmail to Dr A Haque, Botany Department, University of Dacca, East Pakistan

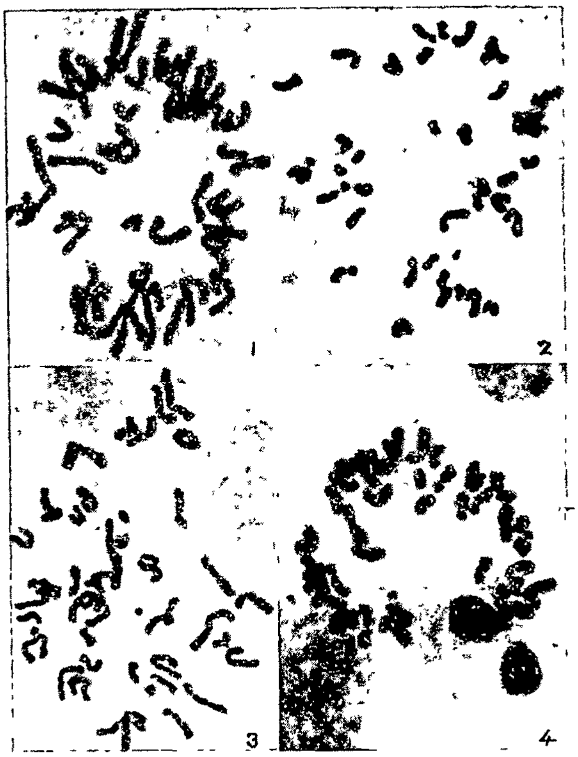

Fig 1 Bone marrow, pre-myelocyte, man (× c 2,140)

Figs 2–4 Spermatogonium of monkeys (Fig 2, × 1,844, Figs 3 and 4, × c 2,140) All acetic alcohol Feulgen squashes Note the small Y chromosome is at 5 o'clock in Fig 2, central in Fig 3, and at 7 o'clock in Fig 4

We wish to thank the following for material and for their very kind help Prof S Zuckerman, Dr A. P. D. Thomson and Dr P Eckstein, of the Birmingham School of Medicine, for the baboon and macaque, Prof E G. T Liddell, Dr. P Glees and Dr. J Cole, of the Oxford Department of Physiology, for the pigtailed monkey, and Dr M. A Nomani of King Edward Hospital, Benares, India, for the human testis fixation

Delayed Toxicity of Radiostrontium in Monkeys

IN a long-term experiment on the effects of low doses of radiostrontium, six monkeys have died following single injections of pure 'carrier-free' strontium-90 of less than 0 2 mc /kgm body-weight The hæmatological findings, and the comparison of survival-times with those obtained in animals which received higher doses[1], are noteworthy

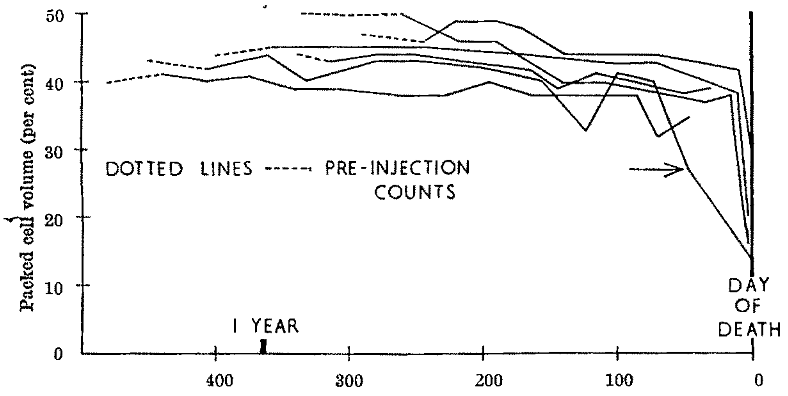

Fig 1

The blood picture in the six animals did not seriously deteriorate following the injections until a sharp terminal fall shortly before death, as shown in the graph of packed cell volume (Fig 1) In four of the animals, the hæmatological findings were within normal limits until two or three weeks before death, and in only one case was there any significant gradual decrease in red blood cell count and packed cell volume before the terminal drop Only in one animal (marked → on Fig 1) was a severe drop in white blood cells observed , the count fell from 13,000/mm ^{3} 46 days before death, to 1,200/mm ^{3} at death. The animals appeared in normal health until about a week before death

In the three animals which were examined histologically, the most severe lesions were seen, as expected, in bone marrow, reproductive organs, and reticulo-endothelial system. Damage in the latter varied widely in the different animals In one animal the spleen exhibited extreme atrophy, whereas in another the germinal centres were large and prominent with numerous mitotic figures present

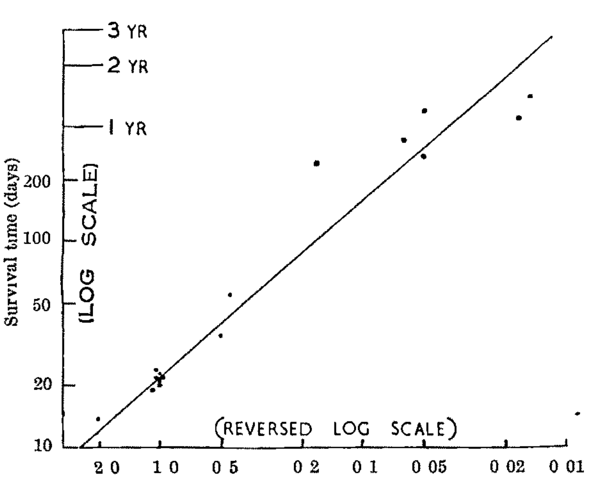

Fig 2

It is notable that the times of survival for the six monkeys fit the straight-line extrapolation of the graph of survival times for the thirteen 'high-dose' monkeys (Fig 2)

All the monkeys were kept on a good mixed diet of medium calcium content, and the radiostrontium content of their fæces and urine was assayed The logarithm of daily excretion was plotted against the logarithm of time T (days) after injection, and from the straight line for the whole period the relationship

$$E \text{ per cent} = 10\,T^{-1\,0}$$

was deduced for the daily excretion, E per cent, of the injection dose. The carcass at death contained an average of 30 per cent of the injection dose

The investigation is continuing, and we intend to report elsewhere on the details of histopathology, hæmatology and radioactivity assays. Observations to date on the twelve surviving monkeys do not conflict with these preliminary findings

Action of Ionizing Radiations on Catalase in Presence of Cysteine, Cystine and Glutathione

FORSSBERG[1] reported that cysteine and glutathione did not protect catalase against inactivation by X-rays, but on the contrary increased the radiation effect on the enzyme Most organic substances act as protectors when added as a second solute to the solution of the primary solute Since cysteine and glutathione have been used in protection experiments *in vivo*[2,3] and *in vitro*[4,5] it was decided to re-investigate the inactivation of catalase by irradiation, in view of the apparently exceptional nature of the effect of these substances

Two types of radiation have been used γ-rays from cobalt-60, and high-energy electrons from a linear electron accelerator Beef liver catalase was irradiated alone and in the presence of cysteine, cystine and glutathione (—SH), and the resultant effects on the enzymatic activity, electrophoretic and chromatographic behaviour and on the ultra-violet absorption were examined

Doses up to 93 × 10^6 ergs/gm were used, and the catalase concentration varied from 2 25 × 10^{-4} gm / ml. to 4 45 × 10^{-3} gm /ml Irradiation was carried out in air, oxygen and nitrogen at pH 7 4 (*a*) Catalase activity was measured by the method of Bonnichsen, Chance and Theorell[6]. All three substances depressed catalase activity *per se*, but protected the enzyme against radiation. At low radiation doses failure to take account of this depressing effect can lead to the apparent result of an increase of the radiation effect.

(*b*) Paper electrophoresis of unirradiated catalase showed a single spot, whereas irradiated catalase gave a comet-shaped streak. When irradiation took place in the presence of cysteine or glutathione, the subsequent electrophoretic pattern was the same as that of the unirradiated solution; that is, one spot appeared in the same position as unirradiated catalase. Protection occurred with cystine too, although to a lesser degree due to its low solubility.

(*c*) The chromatographic behaviour of catalase changed markedly after irradiation. This change did not occur when cysteine or glutathione was present during irradiation, and was not so pronounced when cystine was used.

(*d*) Catalase shows two maxima in the ultra-violet, at 275 mμ and 405 mμ. In the present instance, D_{405}/D_{275} = 0·685. After irradiation the absorption increased at 275 mμ and decreased at 405 mμ, so that D_{405}/D_{275} = 0·226. When cysteine or glutathione was present during irradiation, the absorption did not change.

Thus catalase is protected against γ-rays and high-energy electrons by cysteine, cystine and glutathione. It is noteworthy that the oxidized form of cysteine, namely, cystine, is nevertheless able to compete for the radicals produced by radiation.

This work will be reported in detail elsewhere.

Radiation Dosimetry of Rubidium-86

INTEREST has recently arisen in the possibility of using rubidium-86 as a tracer for potassium in biological studies where the short half-life of potassium-42 presents difficulties[1]. In order that an assessment may be made of the radiation dosage arising from the use of this isotope, the γ-ray output and mean β-ray energy have been measured. Rubidium-86 decays with the emission of a 1·80 MeV. β-ray or by a 0·72 MeV. β-ray followed by a 1·08 MeV. γ-ray[2]. The results reported here indicate that the γ-ray occurs in about 8·4 per cent of disintegrations.

The material produced by neutron irradiation of the purest rubidium chloride at present available contains considerable activity from cæsium-134. A sample of the irradiated material was therefore purified by seven recrystallizations of the acid tartrate, after which only about 0·05 per cent of the disintegrations were due to cæsium-134 (as judged by the subsequent increase in the ratio of γ- to β-ray activity over a period of three months). The disintegration-rate of an aliquot of this material was determined by 4π-ray counting, a method which has been found satisfactory for emitters of relatively high-energy β-rays[3].

The γ-ray dose-rate was measured by comparison against a radium standard, using a graphite ionization chamber, and assuming that 1 mgm. of radium screened by 0·5 mm. of platinum gives 8·3 r./hr. at 1 cm. The emission of β-ray energy was measured by the method of Gray[4], in which the ionization produced in a chamber lined with agar containing a known concentration of the active material is compared with the ionization produced by a standard radium source at known distance. The ionization measurement was related to energy absorption on the assumption that 32·5 eV. is required for the formation of an ion-pair in air. It was found that the average energy emitted as β-rays per disintegration of rubidium-86 is 0·66 MeV., and that the γ-ray dose-rate at 1 cm. from 1 mc. is 0·525 r./hr. An appreciable fraction of the γ-ray effect is due to bremsstrahlung. Since these radiations fall largely in a region where the sensitivity of the chamber changes rapidly with quantum energy, it is not possible to calculate the contribution, but its magnitude can be inferred from the figure 0·025 r./hr. at 1 cm. obtained from 1 mc. of phosphorus-32 under similar conditions.

In view of the closeness of the maximum energies of the β-rays of these two isotopes, it is reasonable to assume that the bremsstrahlung effect is proportional to the square of the maximum energy, when, allowing for the presence of the low-energy branch, the bremsstrahlung of rubidium-86 would give 0·027 r./hr./mc. at 1 cm. The 1·08 MeV. γ-ray therefore gives 0·50 r./hr./per mc. at 1 cm., a figure which leads to the conclusion that the γ-ray is emitted in only 8·4 per cent of disintegrations. Accepting this figure for the branching ratio, and allowing for the forbidden shape of the β-ray spectrum[5], the calculated value of the mean β-ray energy is 0·70 MeV. The discrepancy between this figure and the experimental results is scarcely greater than the uncertainty of the value assumed for the energy of formation of an ion-pair.

A regression line calculated from seventeen observations over a period of 79 days gave a figure of 18·74 ± 0·026 days for the radioactive half-life of a sample of rubidium-86. This reduces to 18·66 days when allowance is made for the 0·05 per cent cæsium-134 initially present.

We are indebted to the Medical Research Council for the loan of the equipment used in the ionization measurements.

Removal of Background in β-Sensitive Nuclear Emulsions

We have tried to reproduce the procedure recommended by H Faraggi[1] and G Albouy[2] for removing the background on Ilford *G*5 plates before experimental exposure The treatment consists in suspending the plates for a certain time in water vapour of a given temperature. After we had made a number of unsuccessful attempts following the methods of other investigators[3], it occurred to us that the small chlorine content of Paris water might be responsible for the difference in the results We tried water containing 12 mgm chlorine per litre for the production of the water vapour, and found that we could remove the background at 60° C in five hours (instead of twenty hours required by the French investigators) without affecting the sensitivity of the plates to subsequent β-rays if the plates were dried after the treatment. α-Tracks withstood this treatment These results seem to throw some light on the process involved.

Details and further experiments under varying conditions will be published in the *Proceedings of the Vienna Academy of Sciences* (*Wien Ber*)

Interaction of Two Constituents in Ferromagnetic Materials showing Reverse Thermo-remanent Magnetism

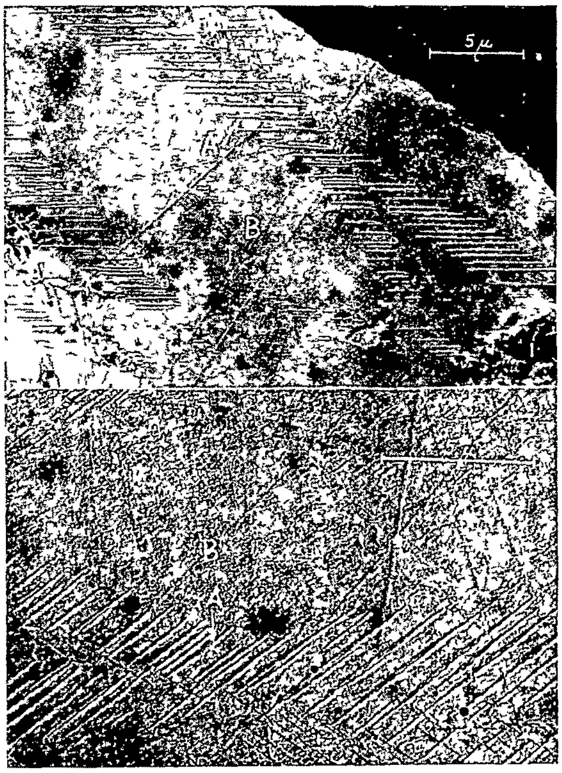
In three earlier communications[1], we described the magnetic, chemical and crystallographic properties of the ferromagnetic minerals causing self-reversal of thermo-remanent magnetization of igneous rocks The results of studies of these properties showed that most grains of ferromagnetic minerals in the Haruna dacitic rocks consist of two different ferromagnetic constituents , one called *A* is titanium-poor titanomagnetite having a crystal structure of inverse spinel type and Curie point around 500° C. , another called *B* is a solid solution of ilmenite and hæmatite (hæmo-ilmenite) having rhombohedral crystal structure and Curie point of about 230° C.

All the magnetic experiments showed that the reversed thermo-remanent magnetism of these minerals and their mother rock is due to the effect of close interaction of these two different ferromagnetic constituents during the process of their cooling in a magnetic field This is in full agreement with Néel's[2] two-constituent theory of reverse thermo-remanent magnetism But it was not clear how these constituents interact with each other in actual mineral grains

It was found, on the other hand, that a simple mixture of these two constituents does not show reversed thermo-remanent magnetism even when the mixture is tightly compressed Therefore, it may be presumed that the relationship of these constituents to each other is a form of intergrowth of one into another, thus resulting in a very close interaction between them.

Figs 1 and 2 show electron-microscope photographs of etched surfaces of ferromagnetic minerals in the Haruna rock. The polished surfaces of the minerals were etched by hydrochloric acid for 15 min , parts of constituent *A* (being approximately magnetite) can easily be etched, but parts of constituent *B* are scarcely affected The original photographs have magnifications of 4,900 (for Fig 1) and 8,000 (for Fig 2) It is clearly shown in these figures that constituent *A* intergrows in echelon into constituent *B* The width of strips of constituent *A* is approximately 0 2 μ. The length of the strips ranges apparently from 1 μ to 5 μ in the photographs , but it seems likely that these strips are more or less linked one to another along specified directions forming fairly long strips of narrow width.

Judging from the above-mentioned scale of strips of constituent *A*, we may presume that each strip consists of a single domain or several domains In other words, the magnetization of these strips may be of the same order as the spontaneous magnetization of constituent *A* Then the magnetic field caused by the strong magnetization of strips of constituent *A* in the neighbouring strips (of mean width 0 5 μ) of constituent *B* will be, on the average, opposite to the direction of magnetization of the strips of *A*, which must be parallel to that of the external magnetic force The detailed calculations cannot be reproduced here, but it can be shown that the magnetic interaction between strips of constituents *A* and *B* mentioned above can result in reverse thermo-remanent magnetization



Intergrowth of constituent *A* in echelon into constituent *B* in a Haruna ferromagnetic mineral

Table 1 CRYSTAL STRUCTURE AND CURIE POINT OF CONSTITUENTS *A* AND *B* IN DACITES AT HARUNA, ASIO AND TOWADA, JAPAN

Locality	Constituent	Crystal structure	Lattice parameter	Curie point
Haruna	*A*	Cubic	A_c =8 403±0 002 A	460° C
	B	Rhombohedral	A_{rh}=5 480±0 002 A α_{rh} =55° 08′±01′	230° C
Asio	*A*	Cubic	A_c =8 397±0 004 A	460° C
	B	Rhombohedral	A_{rh}=5 483±0 004 A α_{rh} =55° 01′±03′	230° C
Towada	*A*	Cubic	A_c =8 412±0 003 A	390° C
	B	Rhombohedral	A_{rh}=5 491±0 001 A α_{rh} =54° 59′±01′	100° C

Thus, it seems that the mechanism of producing the reverse thermo-remanent magnetism in the Haruna ferromagnetic minerals is established It is also true, however, that the presence of these two different constituents, *A* and *B*, in rocks does not always result in the self-reversal of thermo-remanent magnetism As shown in Table 1, ferromagnetic minerals of dacites at Haruna, Asio and Towada in Japan are composed of similar constituents, their magnetic properties closely resembling each other The total thermo-remanent magnetism of the Haruna rocks is reverse, but the total thermo-remanent magnetism of the majority of the Asio rocks is normal at the atmospheric temperature, though there is a distinct tendency towards reversed magnetization of constituent *B* in the latter In the Towada rocks, the total thermo-remanent magnetization is perfectly normal, the direction of constituent *B* being parallel to that of constituent *A* The magnetic interaction between *A* and *B* is strongest in the Haruna rocks and the weakest in the Towada rocks, where it is practically negligible Thus it may be concluded that the self-reversal of thermo-remanent magnetization owing to the two-constituent mechanism can take place in rocks only under the particular condition that ferromagnetic minerals consist of the *A*- and *B*-constituents, and further that they are closely coupled as regards scale of domain, as illustrated, for example, in Figs 1 and 2

An Attempt to observe Whistling Atmospherics near the Magnetic Equator

THE 'whistling atmospheric', or 'whistler', is the most common of the several types of quasi-musical atmospheric that are observed in the audio-frequency band of the radio spectrum It takes the form of a whistling tone that falls steadily in pitch, appearing at about 10 kc /s and falling to about 1 kc /s in the space of 1–4 sec A recently published study of these atmospherics[1], based on observations made at the Cavendish Laboratory, Cambridge, during 1950–51, gives support to the theory of Barkhausen[2] a Eckersley[3], which supposes them to be produced dispersion in the ionosphere of the impulsive atn spheric 'clicks' radiated by lightning strokes T whistlers are thought to travel through the ionosphe in the extraordinary (right-hand circularly polarize magneto-ionic mode of propagation, in which mo at frequencies below the gyro-frequency, the wa are able to penetrate the lower ionosphere withc suffering total reflexion For the details of this thec reference should be made to the sources cited , h it is sufficient to state that the characteristics of t extraordinary mode are found to be strongly fluenced by the earth's magnetic field, and t resulting anisotropy is such that the ray paths the whistlers through the ionosphere must follow t lines of force It is evidently a consequence of t theory that the occurrence and properties of t whistlers should depend on the magnetic latitude the point of observation, and in particular that th should not occur near the magnetic equator, whe the lines of force are horizontal and the waves, the fore, unable to travel up through the lower ionosphe to the less absorbing regions above

In order to test this prediction, one of us (J R has carried out a series of observations in the aud frequency band at Achimota, Gold Coast (lat 6° long 0° 12′ W), which is about 10° north of t geomagnetic equator The atmospherics were receiv on the equipment that was previously used in t experiments at Cambridge The work extended ov about three years, from December 1951 to Mar 1954, and consisted in all of seventy listening perio averaging about 15 min. each Listening was do at varying times of day and night, but especially the late afternoon and evening, which had prov to be favourable times of day for whistlers in t Cambridge records Nevertheless, at no time duri the whole series were any whistlers detected, thou the usual varieties of impulsive atmospheric[4] we plentiful As frequent checks were made of t gain-level and correct functioning of the receiv it is unlikely that any whistlers could ha occurred during the listening periods and escap notice

At middle latitudes whistlers are quite commo and their rate of occurrence is largely independe of time of year[4] In the Cambridge observations t mean rate for all hours was 1 3 per min , while t figure for 1730 G M T , when activity tended to highest, was 3 1 per min During November 195 April 1954, some records of audio-frequency atm spherics at Chelmsford, England, were taken intervals by Isted, in connexion with some studies very high-frequency scatter phenomena[5], and wh no systematic counts of whistlers were made, it w noted that they were maintaining their norm activity (private communication) Thus it is know that during much of the period covered by o observations whistlers were in evidence at midd latitudes, and probable that this was the case duri the remainder It therefore appears that the failu to observe them at Achimota was due to a genui effect of magnetic latitude, in agreement with t theoretical predictions

Change of Elastic Constants in a Superconductor

It is known[1] that there must be a small difference between the elastic constants of a superconductor in the superconducting and the normal states The difference expected is of the order of 1 part in 10^6, but no actual measurement has so far been reported We have now used a statical method to measure the change in the modulus of rigidity of a chemically pure polycrystalline tin wire when superconductivity is destroyed by a longitudinal magnetic field

The specimen was placed vertically in liquid helium, and fixed at the lower end The upper end was connected by a rigid rod to a phosphor bronze wire at room temperature A twist applied to the top of the bronze wire then distributed itself between the two wires according to their torsional constants This equilibrium distribution of strain changed on destruction of superconductivity, and the change was observed by means of an optical lever, as described by Jones[2]. Too much torsion of the tin caused excessive creep, so that the deflexion changes actually measured were less than 5×10^{-7} radians

The results of several runs are plotted in Fig 1 in the form $(G_n - G_s)/G_n$, where G_n and G_s are the rigidities in the normal and superconducting states respectively.

Absolute calibrations are only available for some of the runs Results for the uncalibrated runs have been normalized to fit the calibrated runs at 2° K, and they are thus of help in establishing the dependence of the effect on temperature The full curve represents the function $A\{1 - (T/T_c)^4\}$, where T_c is the transition temperature, and the constant A has been chosen for agreement with the observations at 2° K It can be deduced from work on the change of critical field of tin with stress[3] that the difference in volume between the superconducting and normal states may be expected to be dependent on temperature in this way. This is also in agreement with the work of Lasarew and Sudovstov[4] It can easily be shown that, in any event for a lattice with central forces, the difference in the shear moduli of the two states will depend on temperature in the same way as the volume difference

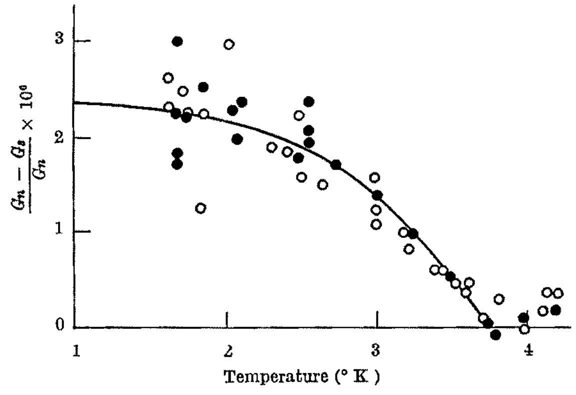

Fig 1 Temperature variation of $(G_n - G_s)/G_n$ for tin ●, Runs with direct calibration, ○, uncalibrated runs normalized to fit at 2° K The full curve represents the function $A\{1 - (T/T_c)^4\}$ with A chosen to fit the results at 2° K

A Phase Diagram for 1 per cent Carbon–Iron Alloys containing up to 16 per cent Nickel

During the course of an investigation into the austenite stabilization phenomena of iron–nickel alloys containing 1 per cent carbon, it became necessary to obtain some knowledge of the limiting solubility of the carbide in the austenite There appeared to be no specific information available concerning the phase relationships of such alloys and, due to the promotion of graphitization by high nickel contents[1], a great deal of uncertainty attends the nature of the iron–carbon–nickel ternary system

Casts weighing 18 lb were made in a high-frequency furnace, the ingots, the analyses of which are given in Table 1, were forged to $\frac{5}{16}$-in diameter rods which were normalized from 1,050° C Specimens were machined, nickel-plated and tempered for 24 hr at 600° C before testing The progress of transformation was followed dilatometrically, using a dilatometer previously described[2], and temperatures measured by means of platinum/platinum–rhodium thermocouples peened centrally into the specimens Readings were taken at 5 deg C intervals with a heating-rate of 1 deg C per min

The results, presented in Fig 1, agree very well with the 1 per cent carbon section which may be

10	0 99	15 8	0 47	0 42

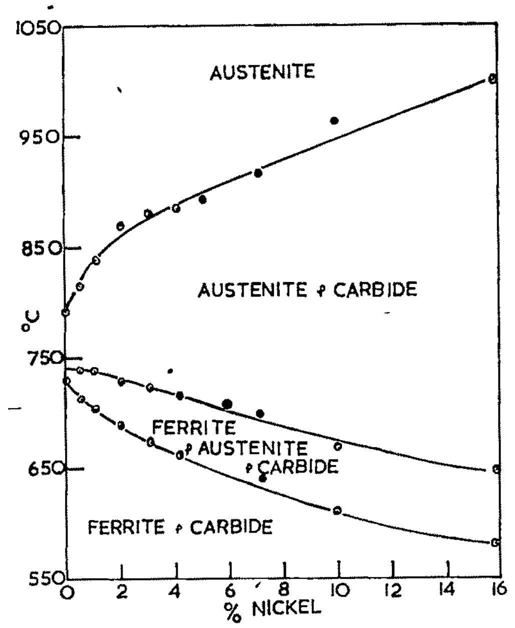

Fig 1 Phase diagram for iron–carbon–nickel alloys containing 1 per cent carbon and 0 3 per cent manganese, heating-rate 1 deg C/min

derived from a ternary diagram based on the assumption of carbide stability Thus Fig 1 does not take into account the presence of graphite, which may be found in the higher nickel alloys The effect of graphitization has been investigated[3] in an attempt to explain an anomalous increase in retained austenite with increasing austenitizing temperatures for certain nickel steels This abnormality was not observed in similar steels produced by carburization[4], a fact which may possibly be explained by the absence of graphite As the latter steels were not prepared from the melt or subjected at any time to very high temperatures, the tendency to graphitize may not have been so pronounced

Graphite was observed in the alloys containing 5 per cent nickel and more, but was not appreciable except in the higher nickel alloys These alloys also gave increased retained austenite contents on quenching from temperatures above those at which all the carbides were in solution Estimates of the graphite content of the 15 8 per cent nickel alloy were made after quenching from various temperatures The results are presented in Table 2 and indicate rapidly increasing solubility of the graphite with increasing temperature of treatment

It is suggested that there is a graphite solubility line above, and roughly parallel to, the carbide line in alloys containing more than 5 per cent nickel

Pronounced depression of the austenite–ferrite transformation on cooling is a characteristic feature of these alloys, and the diagram presented is not generally applicable to transformations on cooling

Table 2 Analysis of Graphite retained on quenching Steel 10 from Different Temperatures

Tidal Forces and the Formation of Hurricanes

Recently, it has been suggested that tidal forces may play a part in the formation of hurricanes[1]. The idea that extra-terrestrial influences may serve in triggering atmospheric phenomena has also received attention from other points of view in recent articles[2,3] However, it is to be questioned whether the hurricane data presented in Prof. C H Smiley's communication offer much support for the tidal hypothesis

Table 1

Dates and total No of hurricanes forming in each 7-day period as given in ref 1		Total No of hurricanes per 7-day period for the period 1886–1951*		
		East of 70° W	West of 70° W	Total
Aug 24–31	28	25	8	33
Sept 1–7	27	27	13	40
Sept 8–14	40	31	17	48
Sept 15–22	28	17	17	34
Sept 23–30	17 5	10	15	25
Oct 1–7	27	18	21	39
Oct 8–14	26	16	23	39

* These data were assembled by Mr J A Colón, University of Chicago They cover a somewhat longer period than those cited by Smiley This accounts for the differences between columns 1 and 4

The number of hurricanes forming per week has been taken from Smiley's communication and is shown in the first column of Table 1 The increase in the number of hurricanes shortly before September 23 and the decrease after that date are cited as evidence that the frequency of formation is in phase with the magnitude of the tidal forces However, a somewhat different distribution is obtained if the hurricanes are split into two groups using the 70th meridian as a dividing line This tabulation, columns 2 and 3 of Table 1, shows that although formations east of 70° decrease substantially after the middle of September, those west of 70° increase even up to the middle of October Data from other areas can also be cited as evidence that no close relation exists between the frequency of tropical cyclones and the magnitude of the tidal forces. For example, data from the north Pacific[4] show that the maximum frequency of typhoon formation occurs about September 1 and shows an appreciable decrease by September 23

The large decrease from the number of hurricanes forming in the September 8–14 period to that for the September 23–30 period, which was shown to be statistically significant by Smiley, is quite interesting, however, since it shows up clearly in the divided data of Table 1 Presumably, this apparent singularity cannot be associated with the tidal forces, since the hurricane frequency increases again after September 30 whereas the tidal force is decreasing. However, it may perhaps be associated with the readjustment of the large-scale flow pattern of the atmosphere which must accompany the westward shift of the preferred area of hurricane formation during late September Charts of the frequency of hurricane formation prepared by Colón[5] show that during September and October the preferred areas of formation in the Atlantic and in the Caribbean – Gulf of Mexico are separated by a longitudinal strip centred on the 70th meridian in which relatively few storms form It might therefore be suggested that the low frequency of hurricane formation during the period September 23–30 is associated with a period when the atmospheric circulation in this region is in a transitional stage between the patterns which are favourable for eastern and western developments From this point of view the singularity, if indeed present, would be the result of significant changes in the atmospheric circulation over the subtropical Atlantic which occur at about the same time each year

CHARLES L JORDAN

[4] Fifth Annual Report of the Typhoon Postanalysis Board, Anderson Air Force Base, Guam, Marianas Islands (mimeographed)

[5] Colón, J A, *Monthly Weather Rev*, 81 (1953)

MR. JORDAN's note suggests that the presence or absence of land has a good deal to do with the formation of hurricanes I am heartily in agreement with this point of view. Hurricanes are essentially oceanic phenomena occurring generally to the east of land masses

The fact that South America crowds north into the Caribbean may account for the interesting result Jordan obtains when he divides hurricanes into those born east and west of long 70° W The northernmost point of South America is at about this longitude West of this point the Caribbean approximates to an nland sea, east of it, one has an ocean open to the east One would not expect to find hurricanes forming in the two areas in exactly the same way, nor would one expect to find atmospheric tides behaving n the same way in both In this connexion, I would point out that if one divides hurricanes into a large enough number of classes, say, according to longitude at birth, one can certainly obscure any trace of a tidal force acting as a trigger within a given class

The arguments offered by Jordan do not seem to concern the validity of my reasoning based on the year-by-year count of hurricanes It would be helpful f a measure of magnitude were available for individual hurricanes, numbers alone do not tell the whole story. Also, there seems to be some question as to whether the available counts of hurricanes and typhoons can be considered reasonably complete For example, on examining the statistics, one suspects that more hurricanes have been found near steamer anes or near inhabited islands than in the open ocean The important activity of weather reconnaissance aeroplanes in recent years may easily have ncreased the average number of hurricanes discovered n a year

If it proves to be true that there is a tendency for two or more hurricanes to form at about the same time in areas widely separated in longitude, the tidal-force trigger concept will be strengthened I do not have at my disposal adequate observational material to carry out this investigation I hope that someone who has both the necessary data and the required mathematical background will look at this problem One remembers that 'Edna' 1954 was coming up along the Atlantic coast at the same time that a severe typhoon was moving in toward Okinawa and Japan. Later, when 'Hazel' 1954 was moving northward, another severe storm, perhaps of hurricane strength, was moving northward in the Atlantic Ocean a long way to the east of the United States east coast

If my estimates of phases and strengths of atmospheric tides are correct, 1955 and 1956 should be good years in which to study this tidal-force trigger concept.

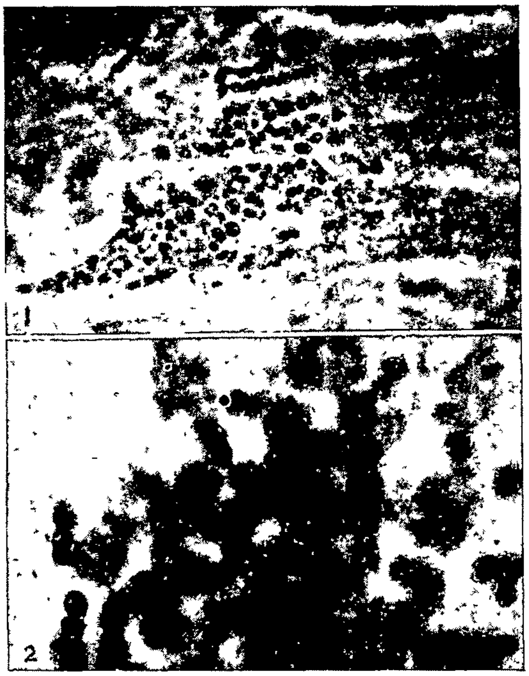
Cytoplasmic Granules in Fibrogenic Cells

A SYSTEMATIC investigation into the method of elaboration of intercellular material in connective and skeletal tissues has shown that cytoplasmic granules, which contain polysaccharide protein components, are present in fibrogenic cells of the fowl embryo both *in vivo* and *in vitro*

When tissue cultures of frontal bone, tendon or cornea are grown by the hanging-drop technique in a fibrin-free liquid medium and viewed in the living state by phase contrast, cytoplasmic granules of 0 7–2 μ in diameter are very conspicuous in the outgrowing cells. Time-lapse ciné-photography has been used to record their behaviour, the granules are seen to cluster around the nucleus and to be in continual motion in the cell processes, where they are often aligned in rows of several granules (Fig 1), they move independently of one another and generally along the axis of alignment Under the oil-immersion lens, the granules show the presence of a less dense centre and in some instances (within the limits of optical resolution) two or more granules appear to join together They persist throughout mitosis and are still plentiful when some intercellular material has been formed On application of janus green, the filamentous mitochondria take up the stain, whereas the granules remain colourless The granules are also stained supravitally by neutral red and gentian violet, which confirms the views of previous investigators[1].

Under the electron microscope, fibroblasts, osteoblasts and osteocytes cultivated directly on electron microscope grids and fixed by osmium tetroxide show granules (Fig 2) closely similar in appearance to those of the living cell, they are seen to have a diffuse margin and are less dense than the smaller, sharply defined lipid globules that are also present[2] Thin sections of cultures cut parallel to the surface of the migrating cells show variations of internal density in the granules, whereas the central zone sometimes appears as a separated region. Similarly, in thin sections of tissues from the embryo, the cytoplasmic granules in fibrogenic cells are seen to be non-homogeneous in structure

It has been found that the granules contain polysaccharide, since after fixation and extraction for



(1) Phase-contrast photomicrograph of part of an osteoblast growing from a living culture of frontal bone, showing the cytoplasmic granules, some of which are aligned in rows Part of the nucleus can be seen on the left of the photograph × 1,500

(2) Electron micrograph of part of a similar cell showing the diffuse periphery of the granules and the denser lipid globules Fixed by osmium tetroxide vapour × 8,000

lipids and glycogen, they remain intact and can be stained by the use of the periodic acid – Schiff technique In sectioned tissue the periphery of the granules appears to stain, while the centre remains colourless, the presence of a free aldehyde is excluded as the periodic acid–Schiff method gives a negative response without prior oxidation The polysaccharide may be acidic in nature, as a positive reaction is obtained by the dialysed iron procedure of Hale[3], but this method may not be highly specific On addition of metachromatic stains (toluidine blue, thionine) to living tissue cultures, the granules show the red–purple of metachromasia within three minutes, this may imply the presence of macromolecules with negative charges It is important to stress that in cultures grown in Tyrode solution alone the outgrowing cells from a tendon explant, for example, still show the presence of metachromatic granules, this would indicate that they have not absorbed metachromatic substances from the normal culture medium in which they are grown These factors suggest that part at least of the polysaccharide content of the granules is mucopolysaccharide In this connexion it is of interest that Gersh and Catchpole[4] have recorded barely resolvable intracellular granules in fibroblasts and postulated that they may be of a glycoprotein nature, and Heller-Steinberg[5] has suggested a similar component in frozen-dried preparations of metaphysial bone cells of the rat, and associated their presence with the deposition of new bone

That the granules contain some protein is suggested first by their ability to take up basic dyes such as eosin, and secondly by ultra-violet microscopy of the living tissues, where there is absorption at 280 mμ while there is no absorption at 313 mμ. In preparations stained by the May Grunwald–Giemsa (Jacobson and Webb[6]) and methyl-green pyronine methods for ribonucleoprotein and deoxyribonucleoprotein, or by the Feulgen technique for deoxyribonucleic acid alone, the granules give no specific staining reaction for either nucleoprotein, nor are the granules destroyed by digestion with ribonuclease or deoxyribonuclease for periods sufficient to remove the known content of ribo- or deoxyribonucleic acid from the cells On the other hand, in living tissue the granules absorb at 265 mμ, this may be due to spread resulting from the 280 mμ absorption, or may indicate the presence of a nucleoprotein which the staining techniques have failed to demonstrate and the nucleases have failed to remove However, so far as can be ascertained, both protein and polysaccharide are present in the same granule

The granules give an alkaline phosphatase reaction by the use of the Gomori–Takamatsu technique, which may well be correlated with the known phosphatase activity of fibrogenic tissue This suggests that enzyme activities may be localized within the granules, while the existence of other components cannot at this stage be excluded

As the cytoplasmic granules persist throughout all stages of growth of the tissue, it is reasonable to associate their presence with the elaboration of the intercellular material. It is therefore suggested that the polysaccharide and protein components of the granules may have fibrogenic properties, the granules may secrete, not necessarily continuously, a part or the whole of the ground substance, they may synthesize the collagen fibril itself, or they may contain precursors for the complex extracellular material. The method whereby the polysaccharide and protein components leave the cell is not yet clear, however, for in the living cell no extrusion of intact granules has been observed

I wish to express my thanks to Prof J T Randall and to Dr H B Fell for their advice and guidance, and to Dr J Chayen for the ultra-violet microscopy

Source of the *Phlei* Growth Factor for *Mycobacterium johnei*

It was first shown by Twort and Ingram[1] that extracts of *Mycobacterium phlei* and certain other acid-fast bacilli contained a growth factor essentia for the laboratory cultivation of *Mycobacterium johnei* They[2] also obtained growth of *M johnei* on media containing alcoholic extracts of certain food materials of cattle Since extracts of organs of cattle did not contain this factor and since the principa lesions of Johne's disease are confined to the intestine they concluded that food was the probable source of the growth factor *in vivo* Francis *et al* [3], however obtained only a very slight stimulation of growth with some extracts of food materials, a stimulation which they considered to be due probably to sub stances unrelated to the growth factor; other extracts gave completely negative results. In all this work a form of inspissated egg was used as the basal medium.

Since it was thought possible that either substances present in food might be altered by enzyme or bacterial action in the gut to growth factor, or that the bacteria normally present there might be a source of that substance, it was decided to repeat and extend the observations of these two groups of workers. This study was facilitated by the availability of modifications[4] of Dubos's media suitable for the cultivation of *M. johnei*.

Materials to be examined were first dried in a desiccator and then extracted with ethanol in a manner similar to that used for extracting *M. phlei*[4]. Each extract was added to media in two-fold falling amounts, the highest final concentration in the media being the equivalent of 100 per cent of the dried material before extraction, and the lowest 1.5 per cent. Aqueous extracts of the dried materials were also studied and, in some cases, fresh unheated Seitz-filtered extracts. The basal media employed were the modifications[4] of the liquid and solid media of Dubos and egg media, to none of which had *M. phlei* extract been added. Two strains of *M. johnei* were used as indicator strains. These would not grow at all on media devoid of *phlei* extract. They were lightly inoculated on to media under test, and incubation was carried out at 37° C. for six months. Extracts of the following were examined.

(1) Muscle, liver, pancreas, mesenteric and bronchial lymph nodes, intestinal wall, rumen contents and intestinal contents of ten healthy cows. The diet of five of the cows for some time before slaughter had consisted mainly of fresh grass. The others had been fed on hay, kale and various concentrates.

(2) Rumen contents, intestinal contents and mesenteric lymph nodes of two cows that had died from Johne's disease.

(3) Broth cultures of rumen and intestinal contents of two healthy cows and two that had died of Johne's disease.

(4) Intestinal contents of three sheep, three pigs, three horses and three rabbits.

(5) Five specimens of commercial dried grass meal, five of fresh grass, three of milk and two of oats, wheat, lucerne, clover, kale and hay.

No visible growth of *M. johnei* occurred on media containing any of these extracts.

These results do not support the view of Twort and Ingram that food materials are the probable source of the growth factor *in vivo*. It is more probable that the production of this factor is restricted to acid-fast bacilli and that, as suggested by Francis *et al.*, *M. johnei* does not require a supply of growth factor from an external source when growing *in vivo*, but can synthesize it as adapted strains do *in vitro*. This observation is of significance when the control of Johne's disease is considered.

Effect of Vitamin A Deficiency on the Cerebro-spinal Fluid Pressure of the Chick

ANIMALS reared on a diet deficient in vitamin A suffer from a syndrome characterized by the appearance of muscular inco-ordination and weakness, followed by paresis, fits and finally death[1]. This condition occurs in poultry, and has been regarded either as a primary disorder of the central nervous system[2], or alternatively as produced by the compression of a normally growing nervous system by an abnormally growing skeleton[3]. In a preliminary series of experiments, we repeated the work of Wolbach and Hegsted[3], using a diet containing no detectable provitamin A. During the course of these experiments, we found that the cerebro-spinal fluid pressure in the experimental chicks was considerably raised (180–200 mm. of water) as compared with that of a group of control chicks on the same diet with the addition of an adequate supply of vitamin A (90–105 mm. of water).

Further experiments were designed to determine more accurately the relationship between the cerebro-spinal fluid pressure and hypovitaminosis A. Day-old chicks were placed on the following diet: white maize 56 parts, wheat middlings 25, casein 12, dried yeast powder 4, calcium carbonate 1, bone flour 1, salt 1. 180 B.S.I. units of vitamin D_3 was added to each pound of the mash, and the diet was also supplemented with vitamin K and riboflavin. This diet contained 1.6 p.p.m. of carotene. The chicks were weighed twice weekly and showed normal gain of weight. Cerebro-spinal fluid pressure measurements were made on these chicks at various ages and the results are shown in Table 1.

Table 1

Age of chicks in days	No. examined	Mean pressure of cerebro-spinal fluid (mm. water) Standard error in brackets
30	4	108 (16.8)
62	21	157 (7.3)
88	7	180 (12.6)
125	3	212 (19.3)

(Standard errors are based on a pooled estimate of variance within groups.)

Measurements on ten normal chicks of comparable ages confirmed that the average pressure of the cerebro-spinal fluid in the healthy chick is less than 100 mm. of water[4]. Thus the cerebro-spinal fluid pressure in the experimental chicks was raised well above normal values. A statistical analysis of the results showed that there was a constant rate of increase of pressure with age, of estimated amount 1.03 mm. per day with standard error 0.243 (31 degrees of freedom, $P < 0.001$). None of the experimental chicks showed any visible signs of neurological disease at the time when the cerebro-spinal fluid pressure was measured, and at necropsy no bony abnormality was found.

Raised cerebro-spinal fluid pressures in vitamin A deficiency have previously been reported in the calf[5], the sheep[6], and the pig[7]. These findings, together with those reported above, indicate that a raised cerebro-spinal fluid pressure is one of the earliest manifestations of vitamin A deficiency in experimental animals, and that it may make its appearance before any overt sign of neurological disturbance becomes evident.

This work was supported by a grant from the Nuffield Foundation. We wish to thank Mr. H. E.

Daniels for the statistical analysis, and Miss M Ellington for technical assistance

Carotenogenesis in *Haematococcus pluvialis*

IN a recent communication[1], Goodwin and Jamikorn state that light is necessary for the synthesis of astaxanthin, the carotenoid responsible for the red colour in the alga *Haematococcus pluvialis* It is not clear whether this conclusion is reached as a result of their own experience or whether they are referring to earlier information[2] In my opinion the conclusion is erroneous, for the following simple experiment convincingly demonstrates that dark synthesis is possible The medium consists of 50 mgm /l soil extract (1 per cent v/v of an extract yielding 5 gm dry-weight of humic substance per litre on acidification), containing an amount of metabolizable nitrogen equivalent to 5 mgm /l potassium nitrate, and is enriched with 500 mgm /l anhydrous sodium acetate A single green motile cell placed in 6 ml. of this medium multiplied, in complete darkness at 13–18° C. with a relative growth-rate ($\log_2$ increase per day) of 0 55–0 6, to a maximum of $2^{14\,3}$ cells per ml in thirty days, further increase being prevented by nitrogen depletion At this juncture the cells were still motile and green Astaxanthin first became visible in the cells on microscopic examination fourteen days later, that is, on the forty-fourth day of the experiment Encystment was complete after a further ten days, by which time enough astaxanthin had accumulated for the cells to appear bright orange to the naked eye

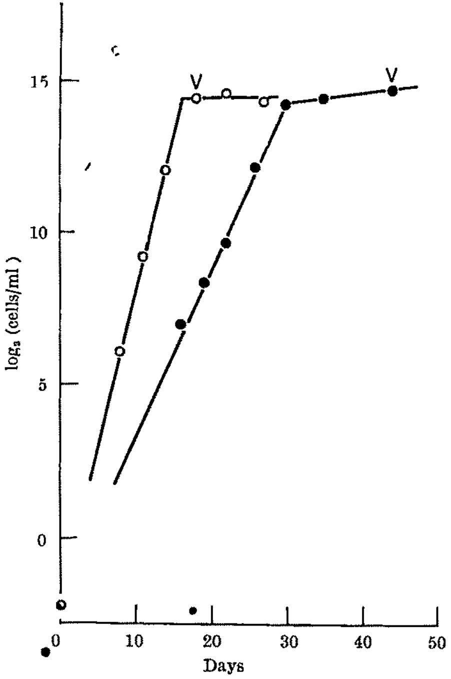

Fig 1 Growth of *H pluvialis* from a single cell in the soil extract medium with 500 mgm /l sodium acetate Open circles, in the light, closed circles, in the dark The arrow-heads indicate the first appearance of the carotenoid in the cells on microscopic examination

A comparison of these rates with those obtained in identical media in the light reveals quantitative differences (Fig 1) In the light, the carotenoid first appears not more than two days after the completion of growth For clear-cut results, conditions have to be such that exponential increase continues to the point when nitrogen becomes limiting, a condition which is met by the medium quoted The relative growth-rate in this medium, with a light intensity of 100 ft candles and with carbon dioxide remaining in equilibrium with the atmosphere, is about double the dark-rate On the other hand, the rate of astaxanthin synthesis, estimated on the time interval between arrest of growth and first appearance of the carotenoid on microscopic examination, appears to be some seven times greater in the light

However, a mere difference in magnitude between the ratios of the two rates is insufficient to prove that light is necessary for astaxanthin synthesis, or, indeed, has any action other than indirectly through the photosynthetic apparatus

It is important to stress that dark synthesis can be overlooked for the reason that, when comparing light- and dark-cultures of the same age, the light-culture is invariably more advanced than the dark and so reaches the point at which the accumulation of the red carotenoid begins (that is, when cell-division ceases) much sooner than the other

Saccharides of Different Varieties of Indian Rice

THE saccharides of seven rice samples (*Oryza sativa* Linn), including some old ones that are in common domestic use, have been investigated, with the view of correlating the carbohydrate changes in stored rice with the nutritive value and taste Four kinds of raw rice (basmati) and three types of parboiled rice (saila) were chosen (basmati and saila are the local names for raw and parboiled rice respectively in northern India) Among the raw rice were included two one-year old samples, one new sample and a fourth that had been stored for three years in tins (30 ± 5° C) The parboiled rice consisted of the varieties Burdhwan, Mainpuri and Patna

Circular paper chromatographic technique, as described by Giri and Rao[1], was adopted The resolution of the saccharides was effected by spotting 50 µl of the water extract of each sample on the circumference of a circle drawn at the centre of a circular Whatman No. 1 filter paper (33 0 cm diam) Along these were also run a mixture of known sugars, including maltotriose and maltotetraose, recently isolated by Whistler and Hickson[2] from corn syrup

Table 1

Sugars	Known mixture	Raw rice				Parboiled rice		
		Basmati 1 yr old B_1	Basmati 1 yr old B_2	Basmati new B_3	Basmati 3 yr old B_4	Saila 1 yr old (Burdhwan) S_1	Saila 3 yr old (Mainpuri) S_2	Saila 1 yr old (Patna) S_3
Fructose	1.0	1.10	1.11	1.11	1.09	1.09	1.10	1.10
Glucose	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00
Galactose	0.93	0.93	0.92	–	0.90	0.91	0.90	0.91
Sucrose	0.80	0.80	0.79	0.79	0.78	0.79	0.80	0.79
Maltose	0.70	0.69	0.69	–	0.64	0.64	0.64	0.65
*iso*Maltose	–	–	–	–	0.54	–	0.54	–
Raffinose	0.51	0.52	0.52	–	0.50	0.50	0.50	0.51
Maltotriose	0.51	0.52	0.51	–	0.50	0.50	0.50	0.51
Maltotetraose	0.40	–	–	–	0.40	–	0.40	–

After irrigating the chromatogram with *n*-butanol – acetic acid – water[3] (40:10:50) for 16 hr., the sugars were located by spraying with aniline-diphenylamine phosphate[4]. The separation of various sugars is shown in Fig. 1, and Table 1 represents the corresponding R_G values.

The *iso*maltose bands in B_4 and S_2 were yellowish-brown in colour, similar to glucose, but quite distinct from the blue colour given by maltose, maltotriose and maltotetraose. Raffinose bands were brown, and those containing a mixture of raffinose and maltotriose dirty-blue. The tri- and tetra-saccharide bands were further confirmed by eluting them with water from a separate chromatogram, hydrolysing with 0.5 *N* sulphuric acid and subsequent neutralization with barium carbonate.

Mixed chromatograms were run with the test samples and the known sugars using *n*-butanol – acetone – water (20:70:10) as the developing solvent.

It is interesting to note that no *iso*maltose, maltotriose and maltotetraose were detected by Williams and Bevenue[5] in American-grown rice samples. This seems to have been due to the fact that their rice samples were not so old, and no enzymatic degradation of starch had taken place.

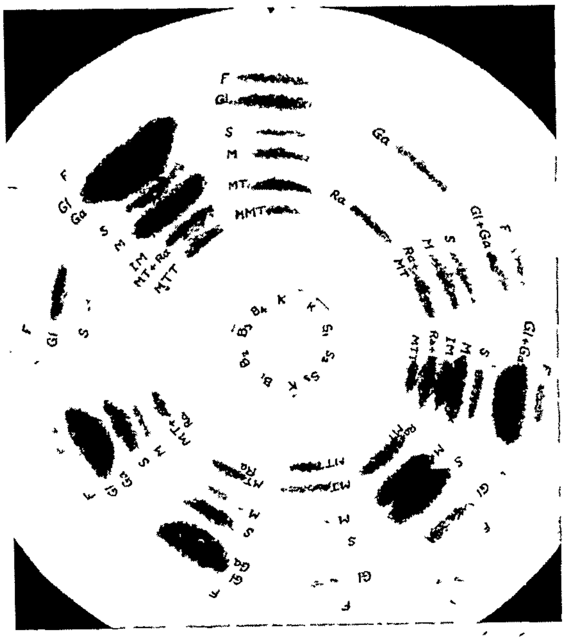

Fig. 1. Circular paper chromatogram showing the separation of saccharides of different rice samples. *K*, known sugars; *F*, fructose; *Gl*, glucose; *Ga*, galactose; *S*, sucrose; *M*, maltose; *IM*, *iso*maltose; *Ra*, raffinose; *MT*, maltotriose; *MTT*, maltotetraose

It has been observed that fructose, glucose, galactose and sucrose are common in almost all varieties of rice. Galactose is not detected in new raw rice. Raffinose is more abundant in parboiled rice (saila). Storage results in the production of a greater proportion of these lower saccharides. The formation of maltose, *iso*maltose, maltotriose and maltotetraose in old samples is possibly due to the action of α-amylase on starch.

These changes in old rice may contribute towards its improved digestibility and better taste, in conformity with the views of Sahasrabuddhe and Kibe[6].

Thanks are due to Dr. R. L. Whistler, of Purdue University, United States, for kindly supplying maltotriose and maltotetraose.

Shikimic Acid in Grass

IN a paper describing, *inter alia*, the isolation of quinic acid from grass[1], it was suggested that one of the acids (termed 'acid *B*') present in the grass extracts might be shikimic acid or a closely allied acid. Acid *B* appeared to be identical with 'acid *G*' found by Davies and Hughes[2] in grass and stated by them to be a monobasic acid of relatively high molecular weight. At the time, only a few milligrams of acid *B* was available in solution, and comparison by paper chromatography with authentic shikimic acid showed that the two acids had the same R_F in butanol – formic acid – water, but in benzyl alcohol – *tert*-butanol – *iso*-propanol – formic acid – water and propanol – ammonia – water the mixed acids gave two spots of closely similar R_F value.

Upwards of 100 mgm. of acid *B* has now been obtained from extracts of a pure strain of grass (*Lolium perenne*) dried at 80° C. in a current of air. This specimen had a melting point of 183–184° C. (corrected), mixed melting point with authentic shikimic acid (kindly supplied by Dr. H. O. L. Fischer) 184–184.5° C. (corrected). The elementary analysis gave C, 47.9; H, 5.65 per cent; calculated for shikimic acid, C, 48.3; H, 5.79 per cent. Molecular weight by titration, calculated as a monobasic acid, was 172.6; shikimic acid has a molecular weight of

174 0 $[\alpha]^{20}_{D}$ for acid *B* was found to be $-$ 179 5° (water, 20 mgm in 0 5 ml), Eijkman[3] gives $[\alpha]^{18}_{D}$ for shikimic acid as $-$ 183 8° (water, C = 4 03 per cent)

Acid *B* and shikimic acid gave identical R_F values (alone and mixed) in the three solvent systems mentioned above It has now been shown that the two spots of closely similar R_F values found previously for acid *B* and shikimic acid were due to contamination of acid *B* with glyceric acid, some, at least, of which was probably formed by the action of the anion exchange resin on the sugars of the original grass extracts during the separation of the acids We have found that even weakly basic anion exchange resins such as 'Deacidite G' react in the 'OH' form with sugars to give several acids, including glyceric acid, which has an R_F value similar to shikimic acid in the three solvent systems used In the present work this difficulty was overcome by using 'Deacidite *G*' in the acetate form for the separation of the acids from the sugars in the grass extracts freed from amino-acid

It is now beyond doubt, therefore, that acid *B* of grass is shikimic acid Work is proceeding on the isolation of the other unidentified acids in the grass extracts, and the results will be reported in detail elsewhere

Effect of α-Naphthalene Acetic Acid on Yield of Indian Cotton

REDUCTION in boll shedding was noticed when injuries to the cotton plant were reported as a result of spraying with 2,4,dichlorophenoxy acetic acid[1] Depletion of non-reducing sugars and accumulation of proteins and amino-acids are common effects of several synthetic hormones[2]. Applications of α-naphthalene acetic acid and certain other growth regulators have been found to effect an increase in the setting percentage of bolls and yield of seed cotton[3] The effects of the applications of these hormones on photosynthetic activity and fruiting with enhanced carbohydrate–nitrogen metabolism in the cotton plant have been recently studied[4]

Most of these observations were made on American or other exotic varieties of cotton A preliminary investigation on the effects of α-naphthalene acetic acid on the carbohydrate changes in the leaves and yield of seed cotton of Dhar 43 (an improved strain of Bhoj, *Gossypium arboreum*) was undertaken during the 1953–54 cotton season An attempt was made to find whether the application of α-naphthalene acetic acid as a spray on desi (Indian) cotton plants would prove beneficial at the active stage of vegetativ growth or at the onset of the reproductive phase The hormone was applied in three doses, of 10, 2 and 30 parts per million

Table 1

Treatment	Yield of seed cotton (lb per acre)	Increase over control	Increase (per cent)
Control	466 2	—	—
Early spray at the active stage of vegetative growth			
10 p p m	567 0	101 4	21 75
20 p p m	537 6	71 4	15 31
30 p p m	516 6	50 4	10 81
Late spray at the commencement of reproductive phase			
10 p p m	582 6	116 4	24 96
20 p p m	593 2	127 0	27 24
30 p p m	569 1	102 9	22 07

Standard error of response over control, 45 8, significant differenc 97 5

Carbohydrate–nitrogen status in the leaves of th plants receiving late spray was higher at certai stages of growth than all other early spray treatment and the control Also, there appears to be mor effective carbohydrate utilization by plants receivin late spray, because of their comparatively highe yield of seed cotton than any other early spra treatments

Early spray of 10 p p m of α-naphthalene aceti acid and all the three late-spray treatments showe statistically significant increase in the yield of see cotton over the control Percentage increases i yield were more in late-spray treatments than i early-spray treatments

These observations are being extended for con firmation and will be published in detail elsewher

We are grateful to Prof R H Dastur, plan physiologist for the Scheme for Cotton Physiologic Research, Indian Central Cotton Committee, fc guidance, the financial support of the Committee fc this investigation is also acknowledged

Distribution of *Pelmatohydra oligactis* (Pallas) in Scotland

SINCE 1918, *Hydra vulgaris attenuata* and *Hyd vulgaris vulgaris* have been cultivated in the Not Dame Laboratory for teaching purposes Ve occasionally these cultures have had to be replenishe from outside sources. It was not until 1946 that noticed the occurrence of *Pelmatohydra oligact* which I felt sure had been introduced in materi obtained from a dealer in the south of Englan The *Hydra vulgaris vulgaris* were completely oust by the rapid spread of *Pelmatohydra oligactis* October 1947 all the specimens were reproduci luxuriantly , even small individuals were covered with testes After this efflorescence, the organisms gave place to *Hydra vulgaris vulgaris*

Although our collecting was by no means exhaustive, and was not primarily for hydra, yet we never recorded *Pelmatohydra oligactis* in our catches. Indeed, I had concluded from laboratory observations that this species required a warmer temperature than that of the Glasgow area It was a great surprise, therefore, to be shown by Mr A MacKinnon (of the Zoology Department, University of Glasgow) a catch of *Pelmatohydra oligactis* obtained by his collectors from water-weeds of a Milngavie pond The circumstantial evidence points to the fact that the species has spread to Scotland Unfortunately, records of the occurrence of *Hydra* in Scotland are not easily obtainable I should be grateful for information of the existence of *Pelmatohydra oligactis* in Scotland before 1940

Enhanced Light Absorption by Compounds in Chromatograms

We have investigated some characteristics of a hyperchromic absorption of light that takes place when a compound in dry chromatographic paper is transilluminated with radiation of absorbable wavelength. Laurence[1] has previously noticed and interpreted such enhanced absorption, but no results were presented, and the phenomenon has escaped general recognition It is a true[2] absorption, and not a manifestation of varying spatial distribution of the transmitted light All evidence indicates that it is caused by transit of photons through dry paper via paths longer than rectilinear lines directly through the paper and the layer of absorbing compound therein Multiple refractions augment the effective optical depth in the manner described by Keilin and Hartree in photometric studies of compounds in devitrified frozen solvents[3]

To evaluate true absorption of ultra-violet light without interference from effects of variable geometrical distribution of the transmitted light, several techniques were applied and found to yield the same results A fluoroscopic photometer[4] was applied in some instances because it intercepts and responds uniformly to the total light transmitted by a papergram For application of other detecting systems, dry Whatman No 50 paper sealed in polyethylene was used to scatter randomly the incident light or transmitted light, or both , the diffuse transmission pattern resembles that of visible light on passage through opal glass[5]

That the hyperchromic absorption is dependent upon light refraction was established by saturating papergrams with oil ('Nujol') and other liquids of refractive index approaching that of cellulose, c 1 5 The absorption of 254 $m\mu$ light was diminished by a factor close to one-third (Figs 1 and 2), and was restored on removal of impregnating fluid by evaporation or by washing with an appropriate volatile solvent Restoration of hyperchromic absorption during evaporation of a volatile liquid was followed kinetically and found to occur simultaneously for several deposited compounds and for absorbing constituents of the paper itself Time curves for increased absorption parallel those for increased scattering of collimated light away from the line of incidence

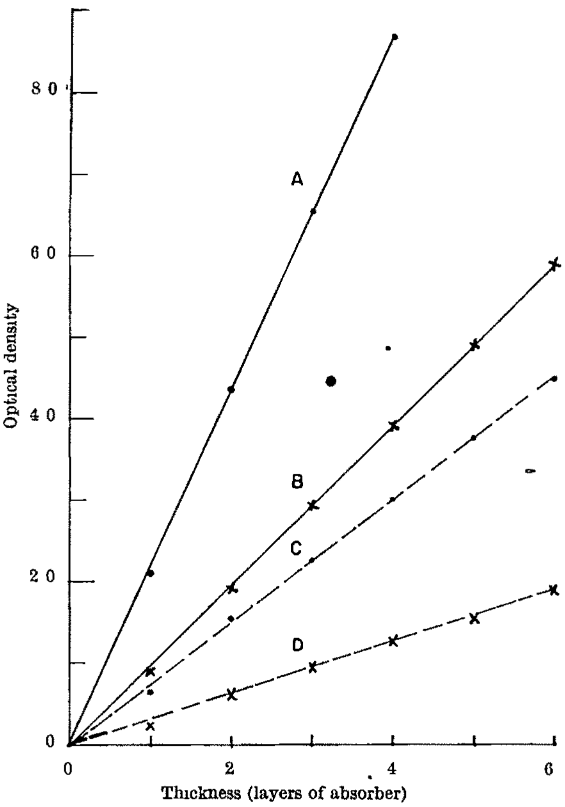

Fig 1 Absorption of light of 254 $m\mu$ as a function of thickness of absorber (*A*) Adenylic acid layer 16 millimicromoles per sq cm thick in dry Whatman No 11 paper , (*B*) dry Whatman No 11 paper , (*C*) adenylic acid of same thickness in oiled paper , (*D*) oiled paper

Typical findings for absorption of light of 254 $m\mu$ are shown in Fig 1, where density was measured with an extremely sensitive photon counter designed for chromatographic densitometry[4] With I_0 at 5,000 photons per sec without absorber, the absorbing layers were inserted between a source of diffuse monochromatic light and the detector Whenever the intensity of light transmitted to the detector decreased to less than 50 photons per sec , the initial photon flux was restored by adjusting intensity of incident light, and the measured density of 2 0–3 0 was added to subsequent values Absorption by constituents normally present in chromatographic papers and by deposits[4] of adenylic acid is seen to follow the Lambert–Beer law

$$\text{Optical density} = E = \log_{10} I_0/I = kt \qquad (1)$$

For absorption per layer of absorber, t represents the number of thicknesses or sheets. To consider absorption of deposited compounds on a molar extinction basis, the thickness is conveniently expressed in dimensions of mass and area[6,7], thus

$$\text{Thickness } (M/1{,}000 \text{ cm}^{2}) = \text{length (cm)} \times \text{concentration } (M/1{,}000 \text{ cm}^{3}) \qquad (2)$$

If dry chromatographic paper is used, the constant, k, may be regarded as a molecular extinction coefficient, ε_s, for a compound in a diffusely scattering matrix While the value of this coefficient is dependent upon properties of the standard matrix used and diminishes in magnitude as the thickness of

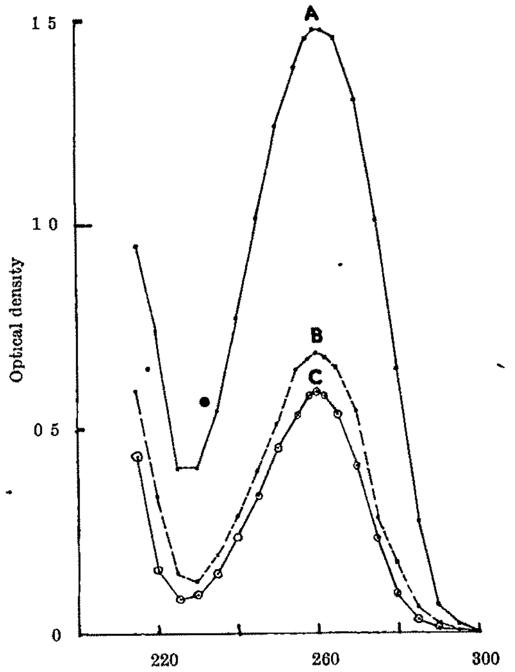

Fig 2 Spectral absorption curves of adenylic acid in paper and solution Thickness of nucleotide, 40 millimicromoles per sq cm (*A*) In dry Whatman No 50 paper, (*B*) in oiled Whatman No 50 paper, (*C*) in neutral aqueous solution

deposit per sheet of paper increases, studies to be presented in a detailed report show a simple relationship to the conventional molar absorption coefficient

E_{254} for a single sheet of dry Whatman No 11 paper is shown to be 1 0 in Fig 1 Corresponding values for Whatman papers No 1, 50, 3*MM* and 3 are 1 3, 1 3, 2 0 and 2 4 respectively For a 16 millimicromole per sq cm layer of adenylic acid in neutral Whatman No. 11 paper, Fig 1 shows that E_{254} is 1 19, and the ε_{s254} is calculated to be 74,000 This exceeds by a factor of 5 2 the value of ε_{254} for adenylic acid in neutral aqueous solution[8]

Conformity of the density to thickness relationships of Fig 1 with the Lambert–Beer law contrasts sharply with results of studies[4,9] wherein multiple thicknesses of absorber were evaluated in single sheets of chromatographic paper Departure from linearity under the latter condition occurs with use of monochromatic light, and is adequately explained on two bases the fractional diminution of optical density due to the presence of relative holes and valleys in a single sheet of paper becomes greater as the average density increases, an effect which is small with papers that are thick, uniform and dry, a second and fundamentally important basis is inherent to the three-dimensional absorption inevitable in a diffusely scattering matrix A linear increase of density with thickness (Equat 1) is theoretically tenable only if each increment of absorber exerts no influence on the fraction of incident photons absorbed by the other layers Such an influence is exerted when successive layers of absorber are added to a single diffusely scattering matrix, that is, a single sheet of chromatographic paper At small thicknesses (Equat 2) of absorber, the average path-length of transmitted photons must be nearly three times the linear distance through the paper due to equal excursions into the two dimensions of the plane of the paper Multiple reflexions from surfaces and total reflexions inside fibres of the paper may further augment the path-length By preferential removal of those photons which are scattered over the paths of greater length, each increment of absorber must shorten the average photon path through all subsequent increments To an ever-increasing extent, the transmitted photons will be members of the small fraction which, in the process of diffuse scattering, happens to be directed along the shortest paths through the paper Hence, the ΔE due to each Δt will become smaller as E increases

While the foregoing considerations preclude rigorous linearity of density to thickness plots for compounds in the form of deposits in a single sheet of paper, empirical relationships can be established with high precision. Reported methods for securing rectified plots[9,10] are of some value, but fail when applied over wide ranges of absorber thickness

Absorption by adenylic acid as a function of wave-length (Fig 2) was estimated with conventional techniques Removal of collimated incident light by the nucleotide was determined by comparison with a blank using the Beckman spectrophotometer with the 4,300 photomultiplier attachment Investigation of other compounds shows that hyperchromic absorption occurs throughout the ultra-violet and visible spectra

Full implications of hyperchromic absorption in chromatographic densitometry remain for future appraisal It is quite constant under standardized conditions, and appears to be a useful property if recognized

Adsorption of Glucose on a Weakly Basic Anion-Exchange Resin

ALTHOUGH furfural[1] is adsorbed on the weakly basic anion-exchange resin 'Amberlite *IR-4B*', the adsorption of sugars has not been reported, in fact, this resin has been used to de-ionize solutions prior to the estimation of sugars[2]. However, following the detection of traces of sugars in the acid fraction from fruit extracts, it has now been found that as much as 1 per cent of the glucose passed through a column of 'Amberlite *IR-4B*' may be adsorbed on the resin.

In studying the adsorption of sugars, two synthetic mixtures of sugars and acids were passed through small columns (5 gm. air-dry resin) of 'Amberlite *IR-4B*' One column had been used many times to collect acids from fruits, the other was freshly packed from a different batch of resin The mixtures of sugars (glucose, fructose and sucrose) and acids (malic, citric, quinic, galacturonic and phosphoric[3]) were similar in composition to those obtained after removing the cations from extracts of pears and peaches. The aliquot used for each experiment contained two or four milli-equivalents of mixed acids and 3 gm of sugars including 0 4 or 2 6 gm of sucrose Following the passage of the sugars and acids, the column was washed with water The first 100 ml was discarded The rest of the washings was collected in fractions some of which were concentrated (usually 100 1) under reduced pressure for paper chromatography

All the fractions run on paper gave a good glucose spot, even after the column had been washed with two litres of water In the case of the mixture with the high sucrose concentration, early fractions gave a good sucrose spot, otherwise only traces of sucrose and fructose were detected All fractions contained quinic or galacturonic acid, or both, depending on their relative proportions in the mixture , the other (stronger) acids were not detected Similar results were obtained with both columns, with rates of washing varying from 0 25 to 2 ml per minute, and after regeneration of the resin with 2 *N* ammonia or 2 *N* sodium carbonate

Some quantitative work was done using solutions of glucose Aliquots were run through the columns, followed by 200 ml of water and then by 50 ml 2 *N* ammonia or 50 ml 2 *N* hydrochloric acid. The water wash recovered 98–100 per cent of the glucose used, the ammonia a further 0 01–0 1 per cent, the acid a further 0 3 per cent Successive washings with 2 *N* hydrochloric acid, allowing the acid to stand on the column, eluted altogether 0 7–1 0 per cent of the glucose used The glucose was estimated by reaction with anthrone[4], using a solution of glucose in 2 *N* hydrochloric acid as a standard in appropriate cases It was necessary to wash the new column thoroughly with 2 *N* hydrochloric acid to obtain a satisfactory blank

Technical assistance by Mr J W Steel and Mr J H Curtin is gratefully acknowledged

Energy of Activation for the Acid-catalysed Hydrolysis of Esters

ACTIVATION energies of the order of 30 kcal /mol have been found for the acid-catalysed hydrolysis of *tert* -butyl 2 4 6 trimethylbenzoate and *tert* -butyl benzoate, for which the reaction has been shown to proceed by alkyl–oxygen fission[1], and of *tert* -amyl 2 4 6 trimethylbenzoate, *tert* -amyl benzoate, diphenylmethyl 2 4 6-trimethylbenzoate and α-methylallyl 2 4 6-trimethylbenzoate, where the same mode of fission may be predicted This value is significantly higher than that found for the hydrolysis of esters by acyl–oxygen fission, and seems to be characteristic of this mechanism

The rate of hydrolysis with acyl–oxygen fission increases markedly from benzoates to acetates, and the transition in mechanism would be expected to occur in the region of *tert* -butyl acetate This appears to be the case, for the Arrhenius equation is not followed in the hydrolysis of *tert* -butyl acetate, the activation energy varying from 26 to 30 kcal./mol between 50° and 100°, which implies, however, predominantly alkyl–oxygen fission, in agreement with the results of Bunton, Comyns and Wood[2] Preliminary experiments on *tert* -butyl formate give an activation energy of *c* 16 kcal /mol , which is normal for the acyl–oxygen fission of esters of aliphatic acids This is consistent with the behaviour of diphenylmethyl formate mentioned by Day and Ingold[3].

A General Method of Aminomethylation

EINHORN discovered that methylolamides condense with phenol (in concentrated sulphuric acid), in accordance with the equation ·

$$C_6H_5OH + R\text{CONHCH}_2\text{OH} \rightarrow C_6H_4(\text{OH})\text{CH}_2\text{NHCO}R + H_2O.$$

$$(R = \text{aryl or alkyl})$$

It has now been shown that the above reaction is a general one which can be used to introduce CH_2NH_2 groups into many aromatic compounds Thus benzene can be condensed, according to the conditions of the experiment, with one or two molecules of the methylolamide giving $C_6H_5CH_2NHCOR$ or $C_6H_4(CH_2NHCOR)_2$ These compounds are readily hydrolysed, with alcoholic hydrochloric acid, to the hydrochlorides $C_6H_5CH_2NH_2HCl$ and p-$C_6H_4(CH_2NH_2)_2 2HCl$ (and another isomer). Some methylated benzenes (toluene, the xylenes and mesitylene) have also been condensed In each case three CH_2NHCOR groups can be introduced into the molecule

Naphthalene also reacts, but the products obtained are difficultly soluble and have not yet been separated

The reaction was successful with the following mono-substituted benzenes chloro-, bromo-, iodo-, cyano-, sulphamido- In each case only one CH_2NHCOR group was introduced Nitrobenzene, benzamide and acetophenone did not react From thiophene the compounds $C_4H_3S\,CH_2NHCOR$-2 and $C_4H_2S(CH_2NHCOR)_2$ were prepared

Details of these experiments will be published elsewhere

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, January 3

British Psychological Society, Education Section (in collaboration with the Conference of Educational Associations, at University College, Gower Street, London, W C 1), at 2 30 p m —Dr Robert Logan "Healthy Youth of To-day—In the Absence of Major Disease What are the Health Needs of Youth ?"

British Museum (Natural History) (in the Huxley Lecture Theatre, Imperial College of Science and Technology, Exhibition Road, South Kensington, London, S W 7), at 5 30 p m —First of a series of twelve lectures on "The Geology and Scenery of South Africa" by Prof Frederick Walker (University of Cape Town) (Swiney Lectures on Geology) Further lectures on Mondays, Wednesdays and Fridays until January 28 *

Tuesday, January 4

Institution of Electrical Engineers, Measurements and Radio Sections (at Savoy Place, London, W C 2), at 5 30 p m —Mr H McGregor Ross "Equipment of Instrumental Accuracy for Recording and Reproduction of Electrical Signals using Cinematographic Film"

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m —Mr C H E Warren "Recent Advances in the Knowledge of Transonic Air Flow"

Tuesday, January 4—Friday, January 7

Geographical Association (at the London School of Economics, Houghton Street, Aldwych, London, W C 2)—Annual Conference

Wednesday, January 5

British Psychological Society, Industrial Section (in Room 105, London School of Hygiene and Tropical Medicine, Keppel Street, London, W C 1), at 1 p m —Mr Robert Sergean "Communication of Information within Management Groups"

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W C 1), at 5 15 p m —Mr N T J Bailey "Some Problems in the Statistical Analysis of Epidemic Data"

Thursday, January 6

Royal Aeronautical Society (at the Institution of Mechanical Engineers, 1 Birdcage Walk, London, S W 1), at 3 p m —Mr P G Masefield "Great Events in Aviation" (Lecture to Young People)

Royal Geographical Society (joint meeting with the Geographical Association, at 1 Kensington Gore, London, S W 7), at 3 p m —Mr F Spencer Chapman "African Journey"

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W C 2), at 5 15 p m —Mr R L Prain "The Copperbelt of Northern Rhodesia" (Henry Morley Lecture)

Institute of Metals, London Local Section (at 4 Grosvenor Gardens, London, S W 1), at 6 30 p m —Prof A H Cottrell "Some Aspects of Twinning and Kinking in Metals"

Friday, January 7

Institute of Physics, Industrial Spectroscopy Group (at 47 Belgrave Square, London, S W 1), at 4 30 p m —Dr R E Richards "The Chemical Applications of Nuclear Resonance Spectroscopy", Dr J Sheridan "Microwave Spectroscopy"

Saturday, January 8

E E G Society (at the National Hospital, Queen Square, London, W C 1), at 10 30 a m —Scientific Papers

British Mycological Society (in the Physics Lecture Theatre, Birkbeck College, Malet Street, London, W C 1), at 11 a m —Scientific Papers

British Interplanetary Society (in the York Hall of Caxton Hall, Caxton Street, Westminster, London, S W 1), at 6 p m —Mr A V Cleaver "Using Hydrogen Peroxide", Mr S Allen "Liquid Oxygen as a Rocket Propellant" *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Engineer (with a good honours degree in mechanical engineering or equivalent professional qualifications, and preferably some experience in research), at the Central Research Establishment, National Coal Board, Isleworth, Middlesex, to carry out research on coal cutting—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S W 1, quoting TT/894 (January 6)

Scientific Assistant (graduate in science or agriculture, and preferably with special training in nutrition and/or a knowledge of foreign languages), for duties which will include abstracting, indexing and proof reading—The Director, Commonwealth Bureau of Animal Nutrition, Rowett Research Institute, Bucksburn, Aberdeenshire (January 8)

Scientist, Grade III (with an honours degree in mathematics, and preferably a qualification in statistics) on the Headquarters staff of the Pneumoconiosis Field Research (Environmental Survey) in London, for duties which will involve the analysis and correlation of statistical data collected by field investigators in the coalfields—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S W 1, quoting TT/895 (January 10)

Assistant Experimental Officer in the Genetics Department, to be responsible for the maintenance of genetic stocks, and to assist the Head of the Department—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts (January 15)

Assistant (female) (preferably with a degree in biology or horticulture, or equivalent qualifications), for field experiments on fruit crops carried out by the Plant Pathology, Entomology and Plant Protective Chemistry Sections—The Secretary, East Malling Research Station, near Maidstone, Kent (January 15)

Mathematician (with H S C (science) or equivalent) at the Ministry of Supply Radar Research Establishment, Malvern, Worcs, to supervise operators using auxiliary punched card machines for scientific calculations and to conduct intricate card handling processes on a high-speed punched card computer—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1, quoting A 362/54A (January 15)

Demonstrator in the Department of Bacteriology—The Registrar, The University, Leeds 2 (January 31)

Senior Lecturer in Physiology, and a Lecturer in Physiological Chemistry, at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (South Africa, January 31)

Lecturer (graduate in science or agricultural science) in Botany at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (Australia, February 1)

H Jones and Co Pineapple Research Fellow (graduate, preferably with an interest in the fields of plant pathology and/or plant physiology) to investigate problems relating to pineapple production in South Africa—The Registrar, Rhodes University, Grahamstown, South Africa (February 28)

Professor of Chemical Engineering in the University of Manchester and in the College of Technology—The Registrar, College of Technology, Manchester 1 (February 28)

Assistant (graduate in organic chemistry) in the Cancer Research Department—The Secretary and House Governor, Mount Vernon Hospital, Northwood, Middlesex

Biochemist (basic grade) (with an appropriate science degree or the A R I C , or an equivalent qualification) in the Group Laboratory—The Secretary, Royal Hospital, Chesterfield

Experimental Officer or Assistant Experimental Officer (with at least H S C in science subjects or Higher National Certificate in physics, or equivalent qualifications), to work in a section dealing with irradiation damage which will involve experimental work in connexion with research on the metal physics of existing and proposed fuels for nuclear reactors—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting 2/103/210

Forestal Land, Timber and Railways Co , Ltd , Research Fellow (with at least a good honours degree in chemistry and preferably some research experience, and particular interest in applying fundamental physical chemistry and physical methods of organic chemistry to problems of industrial importance), at the Chemical Research Laboratory of the Department of Scientific and Industrial Research, Teddington, for research which will be directed to investigating the function of tannins in preventing corrosion of metals—Chief Research Chemist, Forestal Central Laboratory, Harpenden, Herts

Graduate in Physics for experimental work in solid state physics, particularly semi-conductors—The Personnel Officer, Research Laboratory, Associated Electrical Industries, Ltd , Aldermaston Court, Aldermaston, Berks

Laboratory Technician (with experience in a chemical or physical research laboratory, and preferably with some knowledge of vacuum technique), for work in the radioactive isotope laboratory—The Secretary, Barnato Joel Laboratories, Middlesex Hospital, London, W 1

Lecturer (graduate in chemistry or biochemistry and experience in the food industry, preferably in the technology of edible oils and fats or of cereals)—The Registrar, National College of Food Technology, Cranwood Street, City Road, London, E C 1

Senior Scientific Officer or Scientific Officer (with a first- or second-class honours degree in physics), and Experimental Officers or Assistant Experimental Officers (with at least H S C (science) or equivalent qualifications), for the development and operation of a mass spectrometer with emphasis on the analysis of solid materials—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting 2/103/208

THE FARADAY SOCIETY

A GENERAL DISCUSSION
on
MICROWAVE AND RADIO FREQUENCY SPECTROSCOPY
will be held from
April 4–6, 1955, at The University, Cambridge.

The Discussion will be divided into four main sections

- I Microwaves
- II Nuclear magnetic resonance
- III Paramagnetic resonance
- IV Quadrupole spectroscopy

Full particulars regarding application for accommodation and preprints will be issued in due course The Faraday Society, 6, Gray's Inn Square, London, W C 1

A GENERAL DISCUSSION
on
THE PHYSICAL CHEMISTRY OF ENZYMES
will be held from
August 10–12, 1955, at The University, Oxford

The Discussion, which is being arranged by the Colloid and Biophysics Committee of The Faraday Society, will be divided into two main topics

- I Kinetics and mechanisms
- II Characterisation and physical properties

Full particulars regarding application for accommodation and preprints will be issued in due course The Faraday Society, 6, Gray's Inn Square, London, W C 1

The Policy for Education

provides a means of saving for a child's education. For example, for a parent aged 35 next birthday,

The Society pays

£100 p a. for 5 years, beginning in 15 years' time,
and
if the parent dies within 15 years, £100 p a in the meantime towards the child's maintenance

The cost is

£8 7s 6d a quarter for 15 years at most

Enquire for details, giving the ages of parent and child

LECTURES AND COURSES

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

A course of eight lectures
on
MICROSCOPY
will be given on

TUESDAYS and THURSDAYS at 4 p.m, commencing on TUESDAY, JANUARY 25, 1955

A course of practical work will also be given from February 21 to March 18, 1955

This will consist of eight periods of three hours each

Application for admission should be made to the Registrar of the Imperial College, Prince Consort Road, LONDON, S W 7

The fee is 2 guineas for the lectures and 4 guineas for the practical work

SWINEY LECTURES ON GEOLOGY

Under the direction of the Trustees of the
BRITISH MUSEUM (NATURAL HISTORY)

A course of twelve lectures on "The Geology and Scenery of South Africa" by Frederick Walker, Ph D D Sc, in the Huxley Lecture Theatre of the Imperial College of Science and Technology, Exhibition Road, South Kensington, S W 7, on Mondays, Wednesdays and Fridays, at 5 30 p m, from Monday, January 3 to Friday, January 28, 1955 The lectures will be illustrated

Admission free

British Museum (Natural History),
Cromwell Road London, S W 7

BOROUGH POLYTECHNIC

BOROUGH ROAD, S E 1
DEPARTMENT OF CHEMISTRY AND FOOD TECHNOLOGY

1 Surface Chemistry and Colloids Ten lectures by Dr K G Pankhurst Wednesdays from January 19, 1955 7 30 to 9 p m 2 Surface Active Agents—Organic Chemistry and Analysis Ten lectures by a panel of specialists Wednesdays from January 19, 1955 6 to 7 15 p m

For further details apply to the Borough Polytechnic, Borough Road, London, S E 1

BOROUGH POLYTECHNIC

BOROUGH ROAD S E 1
DEPARTMENT OF CHEMISTRY AND FOOD TECHNOLOGY
HUMAN NUTRITION—ENERGY REQUIREMENTS

A course of ten lectures by Dr O G Edholme, Dr J M Hunt, Dr H E Magee, Dr W J Berry, on Mondays, 6 30 to 8 30 p m, January 17 to March 11, 1955

For further details apply to Borough Polytechnic, Borough Road, London, S E 1

BIRKBECK COLLEGE

(UNIVERSITY OF LONDON)
SESSION 1955-1956 BEGINS MONDAY, OCTOBER 3, 1955

Part-time (Evening) Courses provided for Internal Degrees in the Faculties of Arts and Science and for the Academic Postgraduate Diploma in Psychology Facilities also provided for part-time and full-time students reading for higher degrees in arts and science Applications for admission should be made before June 1

Pamphlet and form of application may be obtained from the Registrar, Birkbeck College, Malet Street W C 1

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 *to* 64 *inclusive or a woman aged* 18 *to* 59 *inclusive unless he or she, or the employment is excepted from the provisions of the Notification of Vacancies Order,* 1952

UNIVERSITY OF ABERDEEN

Applications invited for a Research Scholarship in the Department of Chemistry for three years on problems connected with aluminates The research may be submitted for the degree of Doctor of Philosophy The annual value of the scholarship will be between £300 and £600 depending on experience and qualifications, in addition to university fees

Applications, giving full details of qualifications and experience, and the names of two referees, to be submitted to the Secretary, University of Aberdeen, by January 31, 1955

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

Applications are invited for a number of appointments as Research Officer or Senior Research Officer, in the Coal Research Section, Sydney, New South Wales Details of the positions are set out below Position No 480/150 Duties To undertake investigations of the chemical structure of Australian coals and assessment of their potential value to the chemical industry and in particular, to examine the behaviour of coals in various chemical reactions such as hydrogenolysis or to study the chemical reactions occurring during the pyrolysis of coals Qualifications University honours degree in science, with chemistry as major subject and physics to a high standard Experience in the chemistry of natural or polymeric substances would be an advantage Position No 480/153 Duties To participate in the activities of a group concerned with the studying of the mechanical properties of coal and their industrial significance This work involves a fundamental study of coal strength and breaking processes Qualifications University honours degree in science, with physics or mathematics as major subjects or engineering Additional postgraduate research experience would be an advantage Position No 480/154 Duties To participate in studies being undertaken to evaluate combustion characteristics of Australian coals The group concerned is undertaking fundamental studies of combustion processes, clinkering phenomena, and the burning of coal in suspension and in model fuel beds Qualifications University honours degree in science or fuel tech nology Further postgraduate research experience would be an advantage Salary Dependent on qualifications and experience, commencing salary will be determined within the range of Senior Research Officer, £A 1,274 to £A 1,552 per annum nominal (£A 1,472 to £A 1,750 per annum actual), £30 increments, subject to efficiency review at £A 1 366 per annum nominal, Research Officer £A 860 to £A 1,214 per annum nominal (£A 1,058 to £A 1,412 per annum actual), thirteen increments, subject to efficiency review at £A 908 and £A 1,064 per annum nominal Note The above salaries apply to a male appointee, actual salaries include cost of living adjustment which at present increases male nominal salaries by £A 198 per annum The appointment will be conditional on a satisfactory medical examination and the successful applicant will be eligible to contribute to and receive benefits from, either the Commonwealth Superannuation Fund or the Commonwealth Provident Account

Applications, referring to the appropriate appointment number, and stating full name, place date and year of birth, marital state, nationality present employment, particulars of qualifications and experience, and of war service if any, accompanied by copies of not more than four testimonials, should reach the undersigned by January 29, 1955

W IVES,
Chief Scientific Liaison Officer
Australian Scientific Liaison Office,

MATHEMATICAL PHYSICISTS

in the grades of PRINCIPAL SCIENTIFIC OFFICER, SENIOR SCIENTIFIC OFFICER and SCIENTIFIC OFFICER, to be engaged on work in one of the following fields —

1 Astrophysics
2 Fluid Dynamics
3 Nuclear Physics
4 Statistics
5 Solid Mechanics
6 General Applied Mechanics

Applicants should have a first- or second-class honours degree in MATHEMATICS or PHYSICS, together with some years' appropriate postgraduate experience The salary scales are PRINCIPAL SCIENTIFIC OFFICER, £1,125 to £1,507 (male) per annum , SENIOR SCIENTIFIC OFFICER £970 to £1,125 (male) per annum , for SCIENTIFIC OFFICER, £467 10s to £845 (male) per annum , for which starting salary is assessed, according to age, qualifications and experience The successful applicants will be required to join the Authority's Principal Superannuation Scheme to be introduced shortly, and the salary scales quoted will be enhanced to cover contributions Houses available within a reasonable period for married staff who live outside the Establishment's transport facilities Application form from Senior Recruitment Officer, A W R E , Aldermaston, Berks Quote Reference 283/WGE/34

BRADFORD EDUCATION COMMITTEE

TECHNICAL COLLEGE BRADFORD

Applications are invited for appointment as Senior Lecturer in Mechanical Engineering in the College Candidates should be able to offer applied thermodynamics The salary scale for men (according to the Burnham Technical Award) will be from £1,065 to £1,215 per annum

Conditions of the appointment and forms of application may be obtained from the Director of Education, Town Hall, Bradford, 1, and completed forms should be returned to the Principal of the College as soon as possible

A SPALDING,
Director of Education

COLLEGE OF AERONAUTICS

Lecturer required in Department of Aerodynamics, with experience in wind tunnel research work Successful candidate will be required to supervise students' experimental and theoretical research in addition to his lecturing duties He will also be expected to play a leading part in the expanding experimental research programme of the department Salary in accordance with qualifications and experience, with superannuation under F S S U and family allowance

Applications giving full details of qualifications, etc , and quoting the names of three referees, should be addressed to the Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks Further particulars available

---

LONDON TRANSPORT REQUIRES TECHnical Assistants, Central Laboratory, Chiswick Candidates should possess Inter B Sc or equivalent qualification Previous experience advantageous Salary range £300 to £625, with additional payments for certain recognized qualifications Commencing salary according to age, qualifications and experience medical examination , contributory superannuation scheme after probation , certain free travel facilities —Applications to Staff Officer (F/EV 519), London Transport, 55 Broadway, S W 1 For acknowledgment enclose addressed envelope

---

APPLICATIONS ARE INVITED FROM Technicians with a sound knowledge of routine haematology procedures, to fill a vacancy in the undermentioned laboratory The post is established on the Technician Grade, but applicants holding the Institute of Medical Laboratory's Intermediate Certificate will be considered The salary and conditions of service will be as defined by the appropriate Whitley Council —Applications, giving full details, and the names of two referees, should be made to the Secretary, The Laboratory, Peace Memorial Hospital, Watford, Herts

---

UNITED KINGDOM ATOMIC ENERGY AUTHORITY

A E R E , HARWELL, BERKS

Requires an Experimental Officer or Assistant Experimental Officer, to work in a section dealing with irradiation damage which will involve experimental work in connection with research on the metal physics of existing and proposed fuels for nuclear reactors Ample opportunities will exist for original experimental work Minimum qualifications required are higher school certificate in science subjects or higher national certificate in physics, or equivalent qualifications A degree in physics would be an advantage Successful candidate will be appointed either in the grade of Experimental Officer (£715 (minimum age 26) to £880 per annum), or Assistant Experimental Officer (£288 (at age 18) to £640 per annum), according to age, experience and qualifications He will be required to join the Authority's contributory pension scheme, which is to be introduced in the near future and salaries will be increased to cover personal contributions Rates for women are slightly lower

Applications should be sent to Establishment Officer, A E R E Harwell, Didcot, Berks, quoting reference 2/103/210

UNIVERSITY OF THE WITWATERSRAND

JOHANNESBURG SOUTH AFRICA

Applications are invited for appointment to the vacant post of Senior Lecturer in Zoology on the staff of the University Department of Zoology The substantive salary scale attached to the post is £1,100 by £50 to £1,450 The initial salary to be paid to the successful applicant will be determined in accordance with qualifications and experience In addition, a temporary cost of living allowance is paid to married men, the present rate being £234 per annum Duties to be assumed on March 1, 1955, or as agreed upon with the successful candidate An allowance is made towards the cost of travelling expenses

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 The closing date for the receipt of applications, in South Africa and London, is January 31, 1955

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS

Applications are invited from graduates for a post in the Department of Insecticides and Fungicides, to assist in the study of the mode of action of insecticides Candidates should have a knowledge of organic chemistry or biochemistry , previous experience in the field of insecticides is not necessary The appointment will be in the Experimental Officer class with starting salary for graduates between £390 and £690 per annum, according to age and experience Scales for women are somewhat lower Superannuation scheme

Applications, quoting reference 105(2) with names of two referees to be received by the Secretary by January 22, 1955

UNIVERSITY OF NATAL

SOUTH AFRICA

Applications are invited for the post of Director of the Institute for Social Research at the University of Natal, Durban The appointment will be for the two academic years 1955 and 1956 Duties to commence on March 1, 1955, or as soon thereafter as possible Salary £1,600 per annum, plus a temporary cost of living allowance of £234 per annum for married men

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth 5 Gordon Square, London, W C 1 The closing date for the receipt of applications in South Africa and London, is January 31, 1955

RESEARCH LABORATORIES, BRITISH Electricity Authority, Leatherhead, require two General Assistant Engineers Candidates should have a university degree or equivalent qualifications in electrical engineering or in physics Duties include research on electrostatic precipitation and allied problems at Leatherhead and Croydon Laboratories Salary N J B Grade 4, £675 to £850 per annum —Applications, stating age, qualifications, experience, and present position and salary, should be forwarded to D Moffat, Director of Establishments, Winsley Street London W 1, by January 17, 1955 Quote reference NAT /541

THE UNITED KINGDOM ATOMIC Energy Authority, Aldermaston, Berks, requires Experimental Officers and Assistant Experimental Officers, to work in a Technical Library Candidates should have higher school certificate or its equivalent in science or engineering Preference will be given to those who have reached a pass degree standard Experience in a technical library or library qualification would be an advantage The scales of pay are Experimental Officer (minimum age 26) £715 to £880 per annum (male), Assistant Experimental Officer, £288 10s (age 18) to £640 per annum (male) The successful applicants will be required to join the Authority's Principal Superannuation Scheme to be introduced shortly, and the salary scales quoted above will be enhanced to cover contributions Housing accommodation will be available within a reasonable period for married staff who live outside the radius of the Establishment's transport facilities —Application form from Senior Recruitment Officer, Atomic Weapons Research Establishment Aldermaston, Berks Quote Ref 332/WGE/34

TEA RESEARCH INSTITUTE OF CEYLON

Post of Director

Applicants are advised that the closing date for the above post has been extended to January 31 1955

UNIVERSITY OF BRISTOL

Applications are invited for appointment to the Melville Wills Chair of Botany, which becomes vacant on August 1, 1955

Particulars of the appointment may be obtained from the Registrar The University, Bristol, 8

LABORATORY TECHNICIAN REQUIRED for the Electrical Engineering Department for work in the electronics field Commencing salary according to age and experience, in the scale £315 by £15 to £450, plus London weighting (maximum £30) The successful applicant must join the contributory pension scheme —Application giving age and full details of experience, to Secretary, King's College, Strand, W C 2

RADIOGRAPHER REQUIRED AT THE Royal Northern Hospital Holloway Road, London, N 7 to work mainly on clinical applications of radioactive isotopes in therapy and tracer quantities Grading as Senior Radiographer or Radiographer, according to qualifications and experience —Application forms obtainable from Hospital Secretary, which should be returned by January 22 1955

JUNIOR TECHNICIAN, WITH INTEREST in electrical engineering, required to assist in the development and operation of Van de Graaff and neutron generator N C E E or equivalent qualification an advantage Salary according to age and experience —Applications in writing to the Director M R C Experimental Radiopathology Research Unit, Hammersmith Hospital, W 12

BIOCHEMIST (PRINCIPAL GRADE) REquired for Northern Group Hospital Pathological Services Salary scale £1 125 rising by annual increments of £50 to £1,375, plus £50 London weighting —Application forms obtainable from Hospital Secretary Royal Northern Hospital, Holloway Road, London, N 7

TECHNICIAN REQUIRED FOR HISTOlogy laboratory Must have experience in the main branches of histological technique and also in photomicrography Salary according to qualifications and experience —Apply to the Registrar The University Bristol 8 stating salary required

---

BIOCHEMIST SENIOR GRADE (NONmedical) required The successful candidate will be in charge of the routine work in the hospital's laboratory but his main duty will be research work carried out under the Director of Clinical Research Salary in accordance with Whitley Scales viz £835 by £40 to £1 035 by £25 to £1 060 by £20 to £1 080 Small house available —Applications stating qualifications age and experience together with the names of two referees should be sent to the Physician Superintendent Crichton Royal Mental Hospital Dumfries

---

APPOINTMENTS VACANT

HONOURS GRADUATES (FIRST OR second), interested in petroleum research and development work, are invited to apply for two senior appointments as follows 1 Chemist or Physicist, to undertake research investigations of a physico-chemical nature with minimum supervision 2 Chemical Engineer or Chemist, with experience in pilot plant development Candidates should be between 28 and 35 years of age Applications will also be considered from similarly qualified candidates between 23 and 28 for several junior appointments —Box 598, T G Scott and Son, Ltd , 143-147 Regent Street, London, W 1

VACANCIES OCCUR AT RECENTLY established laboratories engaged upon investigations relating to the nutrition of farm animals, for the following Chief Technician for animal house to be responsible for the cleanliness, feeding breeding, and maintenance of small animal stock colonies and to take part in feeding and metabolism experiments Applicants must be males between the ages of 25 and 35 and must be either Associates or Fellows of th Animal Technicians Association Laboratory Technicians are required for a laboratory engaged upon experimental nutrition The work involves both plant and animal biochemistry and limited experience in bacteriological and histological technique will be advantageous Applicants may be either male or female between the ages of 20 and 30 and must hold either the Associate or Fellowship of the Institute of Medical Laboratory Technologists Persons holding a recognized certificate of general education and with at least five years' laboratory experience may also apply —Applications for the positions advertised above should be addressed to "The Head of the Animal Nutrition Research Laboratories, Spillers Limited Middle Aston House, Middle Aston Steeple Aston Oxford"

RECENTLY QUALIFIED CHEMIST, B Sc or A R I C age 20 to 24, required as Assistant to Head of Research and Development Department The work involves both organic and inorganic syntheses up to and including pilot plant Five-day week, canteen facilities —Write to Works Director Thomas Morson and Son, Ltd , Wharf Road Ponders End Middlesex

---

ASSISTANT WORKS CHEMIST, PREFERably a graduate with some experience, aged 25 to 30, for development and control of organic chemical processes Capable of working on own initiative with a minimum of supervision —Apply with full details of training and experience and salary required, to Box 604 T G Scott and Son Ltd 143-147 Regent Street, London W 1

ENGINEER WANTED BY IMPERIAL CHEmical Industries Ltd , Alkali Division, Northwich Cheshire to do research on industrial chemical operations such as heat transfer and matter transfer Candidates aged 25 to 35 should possess an honours degree in engineering (preferably mechanical) and have received such practical training as is required for Associate Membership of the major Engineering Institutions Starting salary according to age and experience — Applications giving details of age and experience should be addressed to the Staff Manager

---

AGRICULTURAL JOURNALISM INTERnational journal seeks successor to present distinguished Editor Applicants must fully appreciate commercial significance of agricultural research Age, salary required, examples of published work and fullest details of education and experience to Box 601 T G Scott and Son, Ltd 143-147 Regent Street, London W 1

QUALIFIED CHEMISTS AND PHYSICISTS with either practical or academic ability are required to work on solid state problems connected with magnetic, semi-conducting and anodic oxides The posts are progressive —Box 602 T G Scott and Son, Ltd 143-147 Regent Street London W 1

RESEARCH DEPARTMENT OF MAJOR OIL Company has vacancies for Chemists or Chemical Engineers at its laboratories in Southern England Applicants must have good honours degree or equivalent with preferably some plant or industrial experience Age up to 30 Salaries appropriate to age and qualifications Good prospects —Write Box 594 T G Scott and Son Ltd 143-147 Regent Street London W 1

ENTOMOLOGIST REQUIRED TO CARRY out field trials overseas and to assist in abstracting and advisory work while in this country — Write giving full details to the Secretary The Murphy Chemical Co , Ltd , Wheathampstead, near St Albans Herts

---

MULLARD BLACKBURN WORKS, LTD

have vacancies for the following —

SENIOR PHYSICAL CHEMIST to ta
charge of the development laboratory wor
ing on ceramic magnetic materials Sor
experience of solid state physics and ch
mistry is essential The work is close
connected with a rapidly expanding indu
try, and offers considerable scope for a
vancement Salary depending upon ag
qualifications and experience, will be with
the scale £800 to £1,100 Ref M/24

SENIOR METALLURGIST required f
Works Laboratory Candidates should ha
a good degree in Metallurgy and conside
able experience in the investigation of fa
tory problems The work will be concern
with the metallurgical problems involv
in the manufacture of lamps and rad
valves, including the production of tungst
and molybdenum Some experience
powder metallurgy would be an advantag
Age 35 to 45 years Salary accordi
to qualifications and experience within t
scale £925 to £1 200 Ref M/26

METALLURGIST to work on the deve
opment of magnetic materials, includ
permanent magnet alloys Applicants shoul
possess a degree in Metallurgy Som
specialized knowledge of physical metallurg
would be an advantage Salary accordin
to age and experience within the scal
£600 to £800 Ref M/25

GRADUATE CHEMIST METALLURG
or Chemical Engin er required to deal with pr
lems relating to the installation of electropla
plant and process control Applicants must h
completed military service and be willing to tra
—Apply Electro-Chemical Engineering Co , L
161 Queens Road Weybridge Surrey

LADY CHEMIST GRADUATE OR H N
required for analysis of electroplating and al
solutions —Apply, Electro-Chemical Enginee
Co , Ltd , 161 Queens Road Weybridge, Sur

ɪITISH CHROME AND CHEMICALS LTD. ire two physical chemistry graduates with re- h experience, preferably in industry, capable ading small teams with energy and persist- . One team to investigate phase relationships ystems at elevated temperatures, the other to with problems of a general nature in electro- istry and surface chemistry, and with the lopment of physico-chemical methods of ysis. Salaries will be according to experience qualifications, and the successful applicants be eligible for membership of an approved ion scheme after twelve months' service.— ications, which will be regarded as confiden- giving the fullest details of experience and fications as concisely as possible, should be essed to W. H. Morrow, Technical Director, sh Chrome and Chemicals Ltd., Urlay Nook. escliffe, Stockton-on-Tees.

0 PER ANNUM AND DEPARTMENTAL sibility offered to Designer with experience , pressure and temperature sensitive in- nts and small electro-mechanical move- Surrey area.—Write, Box 609, T. G. nd Son, Ltd., 143-147 Regent Street, Lon- V.1.

IENTIFIC PERSONNEL OFFICER RE- ed for Dunlop Research Centre near Birm- am, serving the Dunlop Group. Chief duties be the recruitment of graduate staff and the al working arrangements for research person- Should already have experience in the selec- of science graduates for industry possibly on niversity appointments board, and accustomed confer with professors and teaching staff of ersities and technical colleges. Would be re- ed to exercise initiative in contacting managers find out what staff is required, suggesting the s of people to be engaged, deciding where people are most likely to be found and in ing them. This is a high level appointment salary will be appropriate to qualifications experience.—Applications should be made to f Training and Appointments Office, Dunlop bber Company Limited, Fort Dunlop, Erding- , Birmingham, 24.

OOTS PURE DRUG CO., LTD., REQUIRE oman graduate in their Microbiology Division carry out routine assays and investigations into y techniques on antibiotics and vitamins. Ex- ience in this field of microbiology would be advantage and salary will be according to ex- ience and qualifications.—Applications to the sonnel Manager, Station Street, Nottingham.

IEDICAL REPRESENTATIVES. BRITISH idiary of leading American ethical pharma- ical house have vacancies in several areas for ical Representatives. Good starting salary expenses. Car provided.—Applications, with particulars of age, qualifications, experience salary required, in writing only, to the ager, Pfizer, Ltd., 137-139 Sandgate Road, estone, Kent.

DEVELOPMENT CHEMIST IS REQUIRED ork on the applied chemical aspects of pro- and product development in glass fibre manu- are. He will be required to work in close boration with the engineering section in the gn and operation of pilot plant, and to evalu- the properties of new adhesives and coatings glass fibres. There will be opportunities for lamental work in the field of polyester glass inates. Applicants should have a good de- in chemistry, and be between the ages of nd 35 years.—They should write, stating their qualifications, experience and salary re- ed, to the Secretary, Fibreglass, Limited, enhead, St. Helens.

SSISTANT, WITH INTEREST IN PROPER- of matter, required for research on behaviour ackaging materials under shock. A familiarity electronic circuits useful. General certificate education (advanced level) in physics and hematics preferred, with laboratory experience. 5 to £475. Male applicants should have com- ed or be exempt from National Service.— lication forms from Secretary, Printing, kaging and Allied Trades Research Associa- , Randalls Road, Leatherhead, Surrey. (Ref. /2).

IBRARIAN (WOMAN) REQUIRED FOR ial library in progressive firm of petroleum. or chemical engineers. The library is the lligence centre for information in all fields engineering and chemistry, and in matters of le, economics, travel, etc. It is a member of LIB. Applicants should have a science degree preferably some experience of library work a knowledge of French and German. Entry good pension scheme at age 30.—Applications the Secretary, Whessoe Limited, Darlington, ore January 22, 1955.

DESIGN AND DEVELOPMENT

BRITISH OXYGEN ENGINEERING,
LIMITED

Applications are invited for a senior appointment in a Development Group engaged on gas separation projects in a wide and expanding field offering considerable scope to those with special interest in thermodynamics and physical chemistry. Applicants should hold at least a second-class honours degree, and have had previous experience on development or research work. The Company is based in North London, on the North Circular Road, with easy access to main 'bus and train routes. Staff pension scheme. Successful applicants currently resident outside the North London area may be given assistance in obtaining housing accommodation.

Applications should be addressed to the Personnel Manager, British Oxygen Engineering, Ltd., Angel Road, Upper Edmonton, London, N.18.

ELECTRONIC COMPUTERS

Ferranti Ltd., have vacancies for men and women interested in the application of electronic digital computers in problems in: (1) Electrical, Mechanical, Civil and Chemical Engineering, Aeronautics, Crystallography, Nuclear Physics, Optics, etc. Candidates should have first- or second-class honours degrees or equivalent qualifications in mathematics, physics, engineering or chemistry. Experience in numerical methods an advantage. Reference CS1. (2) Accountancy, Actuarial Science, Operational Research, Production Engineering, Statistics, etc. Candidates for these posts should be able to show experience in one of these fields or have qualifications indicating their suitability, for example, membership of appropriate professional body, or first- or second-class honours degrees in mathematics, economics or statistics. Reference CS2. In both groups experience of computing work will be of value, but is not essential. Previous knowledge of electronic computers would not be assumed. Permanent staff appointments with pension benefits.

Application forms from Mr. T. J. Lunt, Staff Manager, Ferranti Ltd., Hollinwood, Lancs.

BOOTS PURE DRUG CO. LTD., HAVE A vacancy in the Research Department for a young graduate for biological work in connection with research on chemotherapy of protozoal diseases and on related topics. Candidates should have a degree in an appropriate biological science. Knowledge of microbiology is essential; some knowledge of biochemistry would be an advantage. Previous research experience in the field of protozoology would be especially valuable.—Applications to Personnel Manager, Station Street, Nottingham.

J. SAINSBURY, LTD., REQUIRE A FOOD Analyst in their Laboratories at Blackfriars. Previous experience in food analysis essential. A minimum salary of £600 per annum is offered. The post will be permanent, and there is a staff pension scheme and full staff facilities.—Applications should be made to the Personnel Manager (F.A.), J. Sainsbury, Ltd., Stamford House, Stamford Street, Blackfriars, S.E.1.

PATENT AGENTS IN LIVERPOOL REquire Technical Assistant willing to work under guidance to qualify in the profession; adequate grounding in electrical engineering or physics essential, preferably to degree standard, for work in telecommunications and electronics; knowledge of German and French an advantage; more important requirements are power of quick and accurate analysis, balanced judgment and clear, unemotional thinking; good prospects for man who is content with predominantly desk work with wide range of interest.—Fullest details to Box 605, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

LEADING OIL COMPANY HAVE VACancy for Chemist in their Head Office. Applicants should be in possession of degree or equivalent, and if possible wide experience in the petroleum industry. Work to cover lubricants, solvents, bitumens, fuels, etc. Age 30 to 35 years. Salary according to age and qualifications.—Applicants should apply, giving full particulars of qualifications and experience, quoting H.3115, to Box 7154, c/o 191 Gresham House, E.C.2.

Advertisers please note. You must add "Apply Employment Exchange" unless the employment advertised or the workers required are excepted under the Notification of Vacancies Order.

LIBRARIAN-INFORMATION OFFICER REquired in Research Laboratories for abstracting, information services and preparation of bibliographies and bulletins. Applicants should preferably have science degree, library experience and knowledge German and French. Position superannuated and five-day week in laboratories shortly moving 20 miles north of London.—Applications, treated in strict confidence to Box 603, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

A LARGE INDUSTRIAL UNDERTAKING requires the services of a Chemical Engineer, to assist in the technical management of an associated company in Norway. A knowledge of electrometallurgy, particularly calcium carbide manufacture, would be an advantage, but is not essential, provided that the candidate has had at least five years' experience in the chemical or metallurgical industries, including some experience as a production executive. The successful applicant will be seconded to the company in Norway for not less than one year, following which an opportunity of service in the U.K. in a similar capacity is likely to arise. Salary will be commensurate with qualifications and experience, but not less than £1,000 per annum.—Details to Box AM7099, AK Advg., Ltd., 212a Shaftesbury Avenue, London, W.C.2.

BOOTS PURE DRUG CO., LTD., REsearch Department, Veterinary Science Division, Thurgarton, require a Laboratory Technician with experience in biological techniques, and preferably with some knowledge of parasitology.—Applications, giving two references, to be sent to the Personnel Manager, Station Street, Nottingham.

FOR SALE AND WANTED

FOR SALE. U.V. SPECTROPHOTOmeter. Hilger Small Quartz Spectrograph and Spekka Photometer; complete with accessories. Excellent condition. £300. Can be inspected by appointment.—B.R.P.R.A., 48 Tewin Road, Welwyn Garden City.

RECORDING MILLIAMMETER REQUIRED. Sensitivity of [illegible] illiampere full scale deflection. Input impedance not less than 3,000 ohms. Pen response approximately 1 second full scale deflection. Chart speed of at least 12 in. per hour.—Anyone having such an instrument surplus and in good working order should write, giving details and price required, to Box 610, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

FOR SALE, HILGER MEDIUM QUARTZ Spectrograph. Type E498, flat field, fitted with Barfit Optical Bench. This instrument has been used for absorption spectroscopy and includes the following accessories: Hilger Spekker Photometer, High Voltage Set for Spark Source. Set of quartz absorption cells, including two Baly tubes and two Hilger Micrometer cells. All in excellent condition.—Box 606, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

MISCELLANEOUS

ESTABLISHED LABORATORY FURNISHER located Newcastle, covering four Northern Counties, Yorkshire and South Scotland, wishes to link up with manufacturers of special equipment for laboratories. Complete facilities offered including sales, technical services and drawing office.—Anyone interested in increasing their turnover please write to Box 597, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

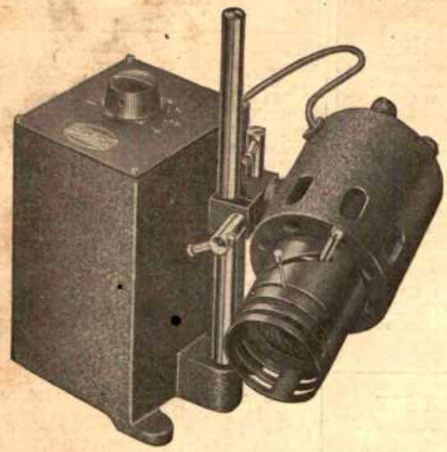
ROBERT GRAVES, ANTONY FLEW AND Naomi Mitchison write in January "Literary Guide," now on sale, 1s.—Specimen copy from Dept. W, 12, St. James's Place, S.W.1.

ELECTRONICS APPLIED TO INDUSTRY. Learn the basic principles and applications with our modern self-study course. Experimental work included if required.—Free Brochure from E.M.I. Institutes, Dept. N.56, London, W.4. (Associated with H.M.V.)

TECHNICAL SERVICES BUREAU SPECIALizes in services to scientific and technical authors. Preparing MS. for press, indexing, proof-reading, translations, secretarial work.—17 Clifford Road, New Barnet, Herts. BARnet 4730.

TRANSLATIONS OF TECHNICAL MATTER on Physical Sciences from French and Spanish.—Waldron, 18 Hayes Close, Chelmsford, Essex.

BECK TENSLITE LAMP



A powerful source for all methods of microscope illumination. Built-in transformer and switch for regulating intensity. Full adjustment for height from table level to 10 in. above, with tilting motion. Centring adjustment for bulb.

Corrected focussing condenser, iris diaphragm and fitting for colour screens. Solid source filament, 6 volt 48 watt for A.C. 200 to 250 volt.

THE TECHNE TEMPUNIT

This self contained constant temperature control unit has been widely sold and in its new form has features that place it in a class by itself. The unique pneumatic control system has all the sensitivity of electrical contact methods with far greater dependability and longevity.

Control is ± .05°C.

Range from room temperature to 96°C.

For full details write to:

STANDARD CADMIUM CELLS

Single and double types in wooden cases or in metal cases as illustrated.

Reliable single or double miniature types mounted in plastic cases, E.M.F. 1.01859 abs. volts at 20° C. Temp. coeff. —40 μV/1° C. Low internal resistance.

Dimensions 3¼ in. × 1⅝ in. × 1$\frac{3}{16}$ in.

Non-temperature coefficient cells for industrial use.

All types of unmounted standard cells can be supplied in quantity from stock.

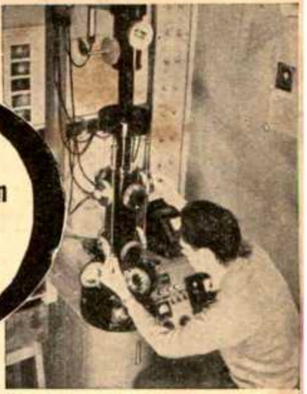
HIGH VACUUM HARNESSES THE ELECTRON

. . . to provide critical information on CRYSTALLINE structures!



Polished diamond facet showing crystalline structure of surface layer

The EDWARDS Electron Diffraction Camera is a striking example of the way in which high vacuum has harnessed the electron for providing critically accurate information regarding surface phenomena during research on lubrication and oxidation, etc., the structure of metals, ceramics, plastics and polymers.

The NEW Edwards camera offers diffraction workers a high performance standard with an ingenious centralized control system—all controls, including that of the remotely controlled H.T. system (to eliminate any electrical interference), are compactly grouped on the camera body.

BRANCHES: GLASGOW & TORONTO. AGENTS THROUGHOUT THE WORLD

Add this skilled worker to your laboratory staff . . .

If you manipulate glass, you need the Scorah Oxy-Coal-Gas Blowpipe—the Blowpipe that gives the right size flame by a simple turn of the turret. It is the most efficient Blowpipe ever produced, and once installed in the laboratory will be in constant use. It will render instant valuable service in making that new idea or gadget, modifying existing apparatus or repairing the little casualties. Your staff will have the opportunity to develop skill in handling 'Pyrex,' 'Phoenix' or 'Hysil' with a tool specially designed to change glass-blowing from a frustration into a fascination. For the more expert it provides much greater speed on the job, plus certainty and mastery via smoothly burning, quiet, stable flames of just the right size for the work in hand.

MUFFLES

Wild-Barfield laboratory tube muffles are of single or twin tube types. Normal maximum operating temperature 1050°C. Two sizes are available, either 12″ or 20″ long, designed for combustion tubes up to 1½″ outside diameter. A tub muffle for high temperatures—1350°C./1400°C.—as well as a range of horizontal rectangular muffles are available. Full details will gladly be supplied.

DORAN

MINI STANDARD CELL

Catalogue No. E.4114

This modified version of the well-known Weston Normal Standard Cell provides a small compact unit which can be used in any position, and is sufficiently robust to withstand considerable rough treatment without ill effect. Experience in manufacture and use over a period of several years has shown it to be completely reliable and stable. The chemical construction, performance and life are the same as that of the H type cell. These cells can be supplied in bakelite case with terminals as illustrated or slightly smaller with soldering posts for instrument mounting.

Further details in List 111

Dim. 4¼″ × ¾″ × ¾″ Weight 2 ozs.

Special purpose Cathode Ray Tubes
for Research and Industry

A range of cathode ray tubes is available for use in specialised applications such as the observation and recording of high speed transient phenomena, where the high capacitances and other limitations of the usual type of instrument tube would result in distortion or complete suppression of the trace.

Typical applications of these special tubes include high voltage cable testing, insulator overload and breakdown testing, cable fault finding by quasi-radar technique and the investigation of high voltage switching phenomena.

They are also suitable for use in laboratory oscilloscopes.

Brief details of some of the more popular types are given below. The tubes are of the all-electrostatic type, with heater ratings of 4V, 1.0A (approx.).

401 CAHA
408 CAHA
Rating.
Va3 (max) 1.5kV
Vp.d.a.3 3.5kV
Sx (av.) 0.090mm/V
Sy (av.) 0.100mm/V
Screen: 401 CAHA. Green-visual
408 CAHA. Killed blue—photographic
Base: B9G (pressed glass)

4cm. dia. high vacuum monitor tubes with one stage of post deflection acceleration. For use in laboratory oscilloscopes, multi-channel strain-gauge recording equipment, etc.

908 BCC
Rating.
Va3 (max.) 10kV
Sx (av.) 400/Va3 mm/V
Sy (av.) 750/Va3 mm/V
Screen: Killed blue—photographic
Base: B12D

A 9cm. dia. flat screen high speed recording tube with a low capacitance deflecting system. The connections to the plates and final anode are brought out through side-arms. Writing speeds of the order of 30,000 km/sec. are possible, and transients of the order of 10^{-9} sec. may be recorded.

908 CARA
Va3 4kV
Vp.d.a. 8kV
Sx (av.) 0.085 mm/V
Sy (av.) 0.12 mm/V
Screen: Killed blue—photographic
Base: B12D

A 9 cm. dia. flat screen high speed recording tube with one stage of post deflection acceleration. For use where the special features of the 908 BCC cannot be employed to full advantage. The Y plate connections and final anode are brought out through side arms.

1601 ABC
Va3 (max.) 5kV
Sx 660/Va3 mm/V
Sy 1100/Va3 mm/V
Screen: Green—visual
Base: B12D

A 16cm. dia. flat screen high speed oscillograph tube. The construction is of the low capacitance type with the deflector plates and final anode connections brought out through side arms.

1608 BCCA
Va3 (max.) 3.5kV
Vp.d.a.3 (max.) 10kV
Sx (av.) 0.15mm/V
Sy (av.) 0.27mm/V
Screen: Killed blue—photographic
Base: B12D

A 16cm. dia. flat screen tube of similar low capacitance construction as the 908 BCC, but with three stages of post deflection acceleration. This tube will achieve similar writing speeds and recording periods as the 908 BCC, and is recommended for use where the deflecting potentials available are limited.

Alternative screens are available including long after-glow and white and blue aluminised types.

Other types of special tubes are available including:

Double gun tubes. Storage tubes.
Television monitor tubes.
Conical deflection systems tubes for radial time bases. Monoscopes, etc.

Write to Osram Valve and Electronics Dept. for full technical details

LEADERSHIP IN LOCAL GOVERNMENT

NEITHER Mr H Morrison, in his book "Government and People a Survey from the Inside", nor the contributors to the symposium on the Civil Service in the current issue of the *Political Quarterly* made more than passing reference to the question of local government in Britain. Mr Morrison, however, referred specifically to one point which deserves further attention and which, if neglected, may well frustrate all attempts to improve the efficiency of the Civil Service and the smooth functioning of the task of government, namely, the serious effects of over-work on Ministers and the senior Civil servants He says "It is a nice point to consider which is the most injurious to the public interest an overworked Minister or an overworked Civil servant" Mr Martin Lindsay comments in similar terms in an article entitled "Government by Endurance".

Both are dangerous and undesirable, and sometimes unavoidable, even if a government does not overload itself or the organization by which the task of government is performed. Mr. Morrison's observations here are a sober warning against over-loading the legislative programme at the behest of a political party without regard to the administrative consequences, and by implication they are a salutary reminder of the need in a democracy for leadership and responsibility. Statesmanship, wisdom and judgment are required to translate a political programme into executive action and legislation, and if they are disregarded through political prejudice or passion, trouble is bound to ensue. Indeed, Mr. Morrison concedes that it is probably more dangerous for the higher Civil servants to be over-worked than for Ministers to be over-worked It is the Civil servants who are responsible for the detailed planning, thinking and drafting, and bad mistakes may be made by them without the Minister being aware of the position

The Crichel Down episode shows that there is some substance in this, even when mistakes have arisen through bad judgment rather than over-work. If, however, the burden on Ministers and on Civil servants is to be reduced, more attention must be given not merely to the administrative structure of the Civil Service and of the Cabinet system, but also to the functions of Parliament and the way they are performed It will not be sufficient merely to see that the programme of legislation is reasonably proportioned to the amount of Parliamentary time available and to the demands it makes alike on Ministers and Civil servants It is essential also to see that, without impairing the essential functions of the House of Commons as the watch-dog over public expenditure and the guardian of individual citizens against official injustice, Parliament is not distracted from its larger duties by demands which could be equally or better met at the regional or local level

The Government's decision, announced by the Prime Minister on November 18, to accept the proposals of the report of the Royal Commission on Scottish Affairs and to transfer to the Secretary of State for Scotland certain responsibilities in Scotland of the Minister of Transport and Civil Aviation, of the Lord Chancellor and of the Minister of Agriculture and Fisheries is a step in the right direction The case for local government reform is in fact closely connected with this need for devolution The importance of Parliament as the great forum of debate on public policy, and the undoubted advantages of centralization in certain technical fields, do not remove the need for vigorous, independent and healthy local government. While it has been necessary from the point of view of the larger public interest to remove such matters as gas and electricity supply, public assistance and health services largely from local government control, the effect on local government should not be regarded without concern. It is essential that the functions of local government should not be thus restricted beyond the minimum that the general interest demands , all that is possible should be done to preserve the vitality of local government and to encourage the individual citizen not only to take a live interest in it, but also to understand it and use the opportunities it affords of influencing policy in matters that directly concern his way of life

Apart from this, the functions of local government have become disproportionate to the finances, organization and areas established for their exercise Frequently, local authorities are either too small to finance the services they provide, or should provide, or too large to manage efficiently the services they finance Moreover, while Mr. Attlee's Government declined to give the Local Government Boundary Commission which it appointed in 1946 adequate instructions, that Government could neither accept the tentative policy suggested by the Commission nor formulate one of its own. Nor has Sir Winston Churchill's Government either formulated a policy or taken any action

When Minister of Housing and Local Government, Mr Harold Macmillan promised to promote any reforms the local authority associations succeeded in agreeing to recommend, and on March 26 expressed a hope that he would present some measure of local government reform during the present Parliament. Meanwhile, the Government has continued the unhappy practice of placing further responsibilities on local government authorities without providing them with the resources to match their responsibilities. It has become manifest that in the matter of national parks, for example, such neglect promises to defeat the whole purpose of the enactment of Parliament , recently the specific proposal has been canvassed that the National Land Fund should be used for national park purposes, at least to the extent of meeting the cost of preserving amenity The Peak Park Planning Board, for example, is seeking the support of the National Parks Commission in pressing for legislation to such an end.

Local government opinion is unanimous that financial reform is even more pressing than structural change, and there is no lack of recognition of the importance of remoulding local government so as to revitalize it. The remoteness of some local government services and the uneconomic character of others may well be due less to the fact that many local government areas bear little relation to real communities, than to the failure to distinguish in status, for the basic local government units, between the extremes of the minor district or borough and the major 'all-purpose' county borough. Apart from this, the services which most closely concern the public and where the local touch can contribute most, such as the social and personal services, like education, maternity, child welfare and other preventive health services, and the care of children and the aged, have been removed from the county districts. Where the local aspects of local government are of most importance, local government has virtually ceased to function.

Unless this is corrected, the real vigour of local government and its roots in the community will be endangered, and thereby parliamentary democracy itself. That was one common theme in the addresses which Mr Attlee and the Archbishop of York delivered at the triennial conference of parish councillors on September 23. Both stressed the value of the small unit in local government, and the dangers attending excessive centralization. Mr Attlee was concerned lest the increasing size of our local government and national units makes our democracy too remote from the people. Dr Cyril Garbett urged that in spite of limited statutory powers, the parish councils could create a strong and healthy public opinion in every parish, and that their freedom of discussion and independence constituted real obstacles against the encroachments of central authority.

Mr Attlee favoured the system of several tiers in local government, rather than bringing such government into the hands of one competent body. This was essentially the solution of the Boundary Commission, which suggested the creation of an intermediate class of 'most-purpose' authority suitable for the bulk of middle-sized and larger towns, irrespective of their present purpose. The 'most-purpose' authority would be large enough for autonomous control of all but the most specialized social services, and would admit extra-local jurisdiction only for impersonal functions requiring wide areas, such as police, fire, ambulance services, public utilities, technical education and major planning work.

What needs to be remembered is that efficiency is not the sole test of local government or the reason for desiring reform. The educational aspect of local government is no less important now than when Mill wrote in the middle of the past century. Indeed, while from the point of view of efficiency, unified administration of large regions is probably more satisfactory than that of a single county was formerly, the educational function of local government is of increasing importance, and any reform of local government should be as much concerned to promote that function as to secure efficient administration.

If local government is in fact to provide the mea by which local groups can manage their own affa and feel that they can influence effectively some the policies that determine their daily welfare, a at the same time provide the training ground f those wishing to enter public life, local governme must not only be local: it must retain and devel functions sufficiently important for it to attract t services of people interested in public affairs. must offer, for example, to the technical or pr fessional man the opportunity of contributi something as a citizen to the course of public affair

Unfortunately, this aspect appears largely to overlooked in the proposals for reform which hav hitherto been canvassed, and the difficulty obtaining unprejudiced candidates of high qualit for local government is also seriously increased b the growing tendency to bring party politics int local government and even into technical question The Association of Municipal Corporations has r affirmed its devotion to the one-tier form of loc authority (the all-purpose county borough), con demned the proposals for the reorganization of loc government issued by associations of county, urba and rural district and parish councils, and asked th Minister of Housing and Local Government t prepare a plan of his own. There appears to be n hope of agreement between the various association as to the one-tier or two-tier, let alone the three-tie systems; but that breakdown does at least aver the danger of a compromise which would disregar the public need and the ultimate purpose of loca government. Mr Harold Macmillan indicated i March that the Government had already done a lo of preliminary work, and the fact that the disput over local government cuts right across party line gives his successor, Mr Duncan Sandys, more scop for manœuvre.

Mr Sandys promised on November 16 to make statement shortly about the Government's intentions and he indicated in reply to a further question tha if legislation was proposed there would be a Whit Paper. It would appear, in fact, that the Ministe now proposes to do what the boroughs have urged to set down in a White Paper the broad principle which the Government has made up its mind t follow, and the discussions which he is having with representatives of local authorities will enabl him to recommend a definite course to be followed The absence of any reference to local government reform from the Queen's speech on November 30, however, suggests that the Government has no intention of introducing legislation dealing with this question during the present session of Parliament.

Pending Mr Sandys's promised statement, there is thus no clear evidence that either major political party is prepared to spare the Parliamentary time and to court the unpopularity that is bound to attend the attempt to deal boldly with local government reform. Meanwhile, although all parties and critics agree that the present system is anomalous and inadequate, and although divisions of opinion cut right across party lines, the burden on central government remains; and at the local end interest dwindles and efficiency diminishes In such a position it is essential for the public, irrespective of party, to urge on whatever minister may be responsible for local government the vital importance of early and firm action to stimulate the renaissance of effective and democratic local government

Local authorities, it should be remembered, have the virtues and vices of all representative bodies , they are part of the method by which people govern themselves, and by which those specially qualified can put their knowledge and skill at the service of the community They encourage and develop responsible citizenship, and their strength is a safeguard against the capture of central government by a would-be dictator They are in touch, moreover, with the circumstances, feelings and needs of their areas, and efficiency in local government would be dearly bought if it destroyed local variety, initiative and responsiveness, and above all the sense of responsibility of the authority to the local electorate

The principles which should determine the attitude of the central government towards local government were well set forth by D N Chester in his book published three years ago dealing with their financial and administrative relations Local government cannot retain vitality unless Parliament and Whitehall trust the local authorities, in the absence of very good reasons to the contrary Minute supervision is incompatible with a sense of responsibility in the supervised it is also expensive in man-power and wasteful Moreover, variety in local action and policy has strength and meaning Variety is a consequence of local independence, of adaptation to differing local views and conditions, and of freedom to experiment , and it is from this point of view that the introduction of party politics into local government may be regretted We cannot have local self-government with complete uniformity or the rigidity of a party caucus Nor need all local authorities be treated alike It is neither good administration nor good democracy to make no discrimination between the varying size and efficiency of existing or future local government units

Of the possibilities open to Mr Sandys or his successor as Minister of Housing and Local Government, the solution recommended by the Local Government Boundary Commission probably offers the best prospect of acceptance The amalgamation of a few counties and the reduction of the number of county boroughs would indeed meet with some objections , but they would be largely discounted by the wide range of functions given to the medium-sized towns and by giving to the counties a few large-scale services Some form of regional authority would, however, be required to provide for the large conurbations such as London, Birmingham, Manchester, Liverpool, Leeds and Newcastle, which now account for some forty per cent of the whole population, and where such services as main roads, open spaces, fire services and water supply can only be planned on a regional basis With the welding of minor authorities into units big enough to resume some of their lost powers, such as those in the social services, and yet at the same time small enough to possess the personal touch and the local knowledge which are indispensable in welfare work—and especially in that among old people—such measures offer a reasonable prospect not merely of establishing reasonable relations between local government and the central authority but also in re-invigorating local authority In this way the attitude of the electorate may be transformed , when local government is able to offer more scope and thus to attract councillors of higher quality, it should have resources adequate for the efficient discharge of its functions, so that it can offer a career with sufficient prospects to attract and retain the services of officers of the highest quality

THE RESISTANCE TO EVOLUTIONARY CHANGE

Genetic Homeostasis

By Prof I Michael Lerner Pp vii+134+3 plates (Edinburgh and London Oliver and Boyd, Ltd , 1954) 12*s* 6*d* net

THE great advances in evolutionary theories which followed the restatement of the principle of natural selection in Mendelian terms can by now be considered classical A new phase of progress is, however, already under way, and to this Prof I M Lerner makes a stimulating contribution in his new book

As he points out, "older evolutionary theories have tended to consider Mendelian populations as relatively uniform, with reserves of variability carried as recessive mutants at individually low frequencies" But more recently "the evidence on concealed variability in natural and domestic populations compels us to view Mendelian populations as being exceedingly heterogeneous aggregates of largely heterozygous genotypes" In fact, we have now come to define the natural sub-units of a widespread species, not in terms of local races of supposedly uniform genetic constitution, but rather as suggested by Dobzhansky, who describes a "Mendelian population" as "a reproductive community of sexual and cross-fertilised individuals which share a common gene pool" This common stock of genes, which is passed around from individual to individual during sexual reproduction, is considered to contain several different allelomorphs at many or most of the possible loci, so that each individual will be multiply heterozygous Most of the allelomorphs, of course, will produce much slighter developmental effects than those commonly used in laboratory work If by selection we concentrate the genes acting in a certain direction, and produce a sub-population which differs from the original one by greater development of some character we are interested in (such as a higher milk yield or production of eggs), we almost invariably find that the sub-population has simultaneously become less fit, and would be eliminated by natural selection It is to this phenomenon that the name 'genetic homeostasis' has been given, implying that if, in a population at equilibrium under natural selection, action is taken (for example, artificial selection) which results in a change in gene frequencies, natural selective processes will be set in motion which tend to restore the gene frequencies to their original value

The main gist of Lerner's book is a thesis as to the mechanism of these homeostatic processes One pillar of his argument is the recognition that the effect which a change of gene frequencies has on the incidence of natural selection will depend on the way the genes affect the development of the individual organisms concerned It is refreshing to find a population geneticist who realizes that he cannot avoid talking embryology and who does his best to do so in a sophisticated rather than an elementary fashion Lerner's next step is to point out that, in organisms which have been submitted to natural selection, development is to some extent canalized or 'buffered' , that is, it involves feed-back mechanisms of such a kind that the normal optimum adult form tends to be produced under a fairly wide range of conditions Then follows the really new point which he is making He argues that this buffering is dependent on heterozygosity, and that when we select for a particular character and thus produce a sub-population with changed gene frequencies, the concomitant lowering of fitness arises because the selection inevitably produces a greater degree of homozygosity, which renders the individuals of the population more at the mercy of chance circumstances during their growth

There is a certain amount of evidence from several different organisms that cross-bred, heterozygous individuals are better buffered in their development than inbred, relatively homozygous ones , and again, there is some evidence, though not very much, that the more efficient buffering is associated with a greater fitness in the face of natural selection The evidence does not, however, all tend in one direction , for example, hybrids between local races of *Drosophila* from widely separate localities are less fit than cross-bred individuals from a single population, though they might well be expected to be more heterozygous It seems probable, indeed, that we have to think of any one natural population as possessing what Dobzhansky has called a "co-adapted gene complex" , that is, a collection of particular allelomorphs which have been selected because they interact together to give rise to well-buffered development The most far-reaching arguments in Lerner's book, however, rather discount the importance of the specific nature of the genes which are heterozygous or homozygous He safeguards himself at various places by stating that the particular character of the genes concerned is, of course, of importance , but he devotes a large part of his exposition to urging that the efficiency of developmental buffering (and therefore the fitness) may depend on the degree of heterozygosity as such, without reference to which loci are heterozygous

In my view this is throwing the baby (the general principle of the specificity of gene action) out with the bath water (the importance of single major genes as opposed to large numbers of less-effective gene differences) One can, for example, easily obtain populations each of which has its buffering lowered in respect of a particular developmental sequel to a specific environmental stimulus, and one can show that the differences between the populations are genetically determined Whether this effect on the buffering is due to homozygosity or not, it must at any rate be brought about by specifically different genes in the different populations Nevertheless, although one feels that Lerner's thesis does not contain the whole truth, it may contain a part of it, and at least point toward some theoretical developments which have not yet been fully worked out We still understand so little about the mechanisms involved in developmental buffering that one would hesitate to deny that Lerner may be correct in suggesting that there is some non-specific effect of homozygosity on that process, even though one retains the belief that there are also specific effects which he seems to pass over rather too lightly In any event, one can only be grateful for such a clear and stimulating discussion of topics which are in the very forefront of scientific advance in one of the most fundamental of all biological fields

C H Waddington

ST. MARY'S HOSPITAL MEDICAL SCHOOL

The History of St Mary's Hospital Medical School
By Sir Zachary Cope Pp x+257+26 plates (London William Heinemann, Ltd , 1954) 25*s.* net

THAT the biography of a medical school reflects, in large part, the history of medical education is well illustrated by the story of St Mary's Hospital Medical School, which last year celebrated its centenary The second youngest of the London undergraduate medical schools and a mere babe compared with some of its associates, its trials and tribulations in the past century have to some extent been a common experience , yet it has, as medical schools do, developed its own personality, and some episodes in its history have been unique It is, for example, the only London medical school which started from a definite plan to build a teaching hospital and medical school at the same time The Paddington area had developed enormously in the first half of the nineteenth century, due mainly to the Grand Junction Canal with its Paddington wharves and to the building of the Great Western Railway terminus For this rapidly growing population there was no hospital nearer than St George's across Hyde Park to the south and the Middlesex Hospital to the east It happened that, at the time of the project for founding a new hospital, Mr Samuel Lane was running a successful private medical school near St George's, but had not achieved an ambition to be appointed on the staff of that Hospital He and some of his St George's supporters were elected to the committee charged with building the new hospital, and no doubt it was this group that advocated the founding of a medical school as part of the plan Indeed, before the hospital could be recognized as a suitable place for clinical instruction of medical students, one of the licensing bodies, the Society of Apothecaries, required that it should have both a resident apothecary and an attached medical school Accordingly, the building for the new School, accommodating some three hundred students and costing £2,500–£3,000, was completed within four months of its commencement in the summer of 1854 It was an inconspicuous building—"hidden away in the space between the hospital, the Great Western terminus, and the canal, it was as difficult to find as Meckel's ganglion".

As the new Hospital grew in piecemeal fashion, the Medical School took roots under a succession of deans, including Ernest Hart, for many years editor of the *British Medical Journal* , W B. Cheadle, who persuaded the Hospital to allocate its share of the School profits for the foundation of entrance scholarships and who, with other St Mary's men, helped to establish the first medical school for women , George Field, who founded a residential college and under whose attractive personality the School at first lourished but later relapsed into the doldrums , and H. A Caley, during whose tenure two important ppointments were made—B E Matthews became School secretary in 1900 and held the post with ncreasing responsibility and quiet efficiency for early fifty years, and Almroth Wright was appointed o the dual lectureship in pathology and bacteriology n 1902, his genius soon imparting a new spirit of nthusiasm to both teaching and research In the ext year, St Mary's unfortunately lost another rilliant teacher and investigator in Augustus Waller, who for nearly twenty years had taught physiology n the School and was the father of the electrocardiograph So, after short terms of office by Clayton Greene and Sir John Broadbent, we come to he man whom Sir Zachary Cope rightly calls "the Great Dean"—Dr. Charles Wilson (now Lord Moran), ater to become a famous president of the Royal College of Physicians and medical adviser to Sir Winston Churchill, but among St Mary's men to be emembered always as the architect who over a quarter-century dreamed and planned and brought nto being the new St Mary's Hospital Medical School After a searing and maturing experience as a regimental medical officer during the First World War, Dr Wilson was appointed as assistant physician o St Mary's Hospital in 1919 and became dean in he following year The outlook for the School at hat time was ominous, particularly as the new dean ad been told by members of the University Grants Committee that St. Mary's had no future as an ndergraduate medical school But Wilson had great qualities, among them the capacity for quick and letermined action The Royal Commission on Undergraduate Education had lately recommended he establishment of full-time clinical appointments, nd although there was no hope of financial support rom the University Grants Committee for such a venture at St Mary's, the dean persuaded two outstanding members of the clinical staff, Dr Wilfrid Harris and Mr Clayton Greene, to become part-time irectors of new medical and surgical units This old step soon had its reward, for the University of London in 1921 agreed to undertake three-quarters f the cost of two clinical units in medicine and urgery, and Dr F Langmead and Mr C. A. Pannett were respectively appointed to be the first full-time rofessors of medicine and surgery

The next great problem was to find bigger and etter premises Here again Dr Wilson so impressed wo rich philanthropists, Lord Revelstoke and Lord Beaverbrook, that between them they contributed early £90,000 which, with a grant from the University of London, allowed the new Medical School to be pened by King George V in 1933 Another great riumph for the dean was the acquisition of the very ne athletic grounds at Teddington, helped again by he munificence of Lord Beaverbrook Meanwhile, Dr Wilson, with his remarkable judgment of character, was steadily improving the quality of the new ntrants to the Medical School By direct contacts with headmasters and college tutors and by personal nterviews with the applicants, he was able to attract o the School a steady influx of young men of high ntelligence, strong character and athletic ability, so hat, in 1934, St. Mary's became the first London School to accept only those students intending to work for a university degree. The social activities f the School also prospered, and by 1945, after wenty-five years tenure of the office of dean, Lord Moran could justly claim that the School had been both materially and spiritually re-created

This documentary study of a medical school is supplemented by chapters on the development of medical specialization in both pre-clinical and clinical education and on the remarkable story of the band of famous men whom Sir Almroth Wright attracted around him in the Inoculation Department (later re-christened the Wright–Fleming Institute), together with biographical sketches of the School's seven Fellows of the Royal Society and of a galaxy of outstanding men (and one woman) who spent some part of their lives in the service of St. Mary's Hospital and its Medical School The author, himself associated with the School for more than half a century, will be gratefully acclaimed by a much wider public than the 'old boys' of St. Mary's for this graphic contribution to the history of medical education.

EXPERIMENTAL NUCLEAR PHYSICS

Experimental Nuclear Physics

Edited by E Segrè. Vol 1. Contributors H Staub, H Bethe and J Ashkin, N F Ramsey, K. T. Bainbridge Pp ix+789. 120s net. Vol 2 Contributors P Morrison, B. T Feld Pp. viii+600 96s. net (New York John Wiley and Sons, Inc., London Chapman and Hall, Ltd , 1953)

THE publication of the two-volume review of "Experimental Nuclear Physics", edited by E. Segrè, provides a much-needed summary of development in nuclear physics to take the place of Prof Hans Bethe's 1937 review of nuclear physics, which at that time rendered a similar service

The review is provided by a distinguished list of authors Prof Hans Staub writes on the development of methods of detecting nuclear particles. The principles and practice of ionization chambers, proportional counters, Geiger–Muller counters, crystal counters, scintillation counters and Čerenkov counters are described as well as cloud chambers or nuclear emulsions. The associated electronic instruments are similarly dealt with and, in particular, fast counting circuits and coincidence circuits One section is devoted to the detection of neutrons by gaseous detectors, boron trifluoride counters and fission detectors

Prof. Hans Bethe and Dr. Julius Ashkin write on the passage of radiation through matter. The range–energy relations for protons and alpha-particles are brought up to date and extended out to energies of 3 BeV. when protons have a range of 10 km. This illustrates the great development in the range of particle energies now available to experimental nuclear physics The range–energy relations are given not only for air but also for hydrogen and different metals A theoretical discussion of range–energy relation is also given with respect to ionization The penetration of high-energy electrons and gamma-rays through matter is also dealt with exhaustively.

In his article on nuclear moments and statistics, Prof Norman Ramsey gives a theoretical discussion on the interaction of the nucleus with atomic and molecular fields, and this is followed by a description of experimental methods of measuring nuclear moments and statistics The methods of hyperfine structure, band spectra and molecular and atomic beams are well described, and the powerful resonance method for molecular beams is discussed Microwave spectroscopy, which has also proved to be a powerful tool, is described. Finally, details are given of all known experimental results on nuclear moments and spins and their regularities, and the significance is discussed Prof Ramsey also contributes a section on nuclear two-body problems and elements of nuclear structure In this section the experimental evidence for the nature of nuclear forces is discussed Results on proton–proton and proton–neutron scattering are surveyed for energies up to 400 MeV., and an account is given of the theories of scattering and the meson theory of nuclear forces Finally, the author gives a brief description of the theory of nuclear shell structure

Prof. K T Bainbridge contributes a section on charged particle dynamics and optics, relative isotopic abundances of the elements and atomic masses The general theory of mass spectrometers is given, including a comprehensive treatment of the different methods of magnetic focusing Typical mass spectrometers including those of Dempster and Nier and Mattauch are discussed. The section concludes with tables of the relative isotopic abundances of the elements and isotopic masses

A survey is given by Prof P Morrison of the vast amount of experimental work on nuclear reactions which has been carried out during the past decade The theories of nuclear reactions and their relation to nuclear structure are also thoroughly discussed A chapter is devoted to nuclear fission and another to nuclear reactions of high energy Prof B T Feld contributes 380 pages on neutron physics, including a bibliography of sixteen pages The interaction of neutrons of energy from thermal energies up to many millions of volts is discussed Experimental techniques of neutron physics are described, and finally the interaction of neutrons with matter in bulk is dealt with, including a chapter on elementary reactor theory.

These two volumes present an encyclopædic survey of the present state of nuclear physics, and should be in the library of all laboratories working on this subject J D COCKCROFT

RADIOISOTOPE TECHNIQUES IN DIAGNOSIS, THERAPY AND RESEARCH

Radioisotope Techniques

Proceedings of the Isotope Techniques Conference, Oxford, July 1951, sponsored by the Atomic Energy Research Establishment Vol 1 Medical and Physiological Applications Pp vi+466+42 plates (London H M Stationery Office, 1953) 50*s* net

SINCE the construction of the low-energy experimental pile (GLEEP) and its successor (BEPO) at Harwell, the Atomic Energy Research Establishments at Harwell and at Amersham have supplied radioactive isotopes for clinical and research purposes in Great Britain and in many overseas countries These Establishments have become, in consequence, informal clearing-houses for problems and ideas relating to the production, manipulation and application of radioactive isotopes For the steadily increasing number of medical and scientific workers and engineers using radioisotopes, it was therefore highly profitable that senior members of the Establishments should organize a conference on radio isotope techniques in 1951 The conference was held in Oxford and was attended by nearly five hundred representatives of some twenty nations The proceedings of the conference have been published in two volumes, the first and larger of which, dealing with medical and physiological applications, is reviewed here

The proceedings contain seventy-one papers together with the discussions which followed their presentation in conference and deal with a very wide range of techniques and applications The papers are grouped under three main headings therapy and diagnosis , biochemistry and metabolic studies and plant biochemistry Papers grouped under the first heading deal mainly with the use of iodine-131 in the diagnosis and treatment of abnormal thyroid function, and the use of such isotopes as phosphorus-32, cobalt-60, and cerium-144 as beta- and gamma ray sources in irradiation therapy Papers under the second heading deal with the use of radioisotopes in biochemical and physiological research and cover such subjects as the use of 'labelled' proteins in immunochemistry and the determination of sodium and potassium in invertebrate nerve fibres by activation analysis The third and smallest group of papers deals mainly with the uptake and distribution of phosphorus-32 in plants either as fertilizer or as labelled insecticides The discussions were frank and constructive, and in some cases constituted a salutary addendum to the preceding paper

The papers dealing with the medical applications of radioisotopes in diagnosis and therapy suggest that much has yet to be learned about the use of pile-produced radioisotopes for the selective destruction of tumours *in vivo* As a diagnostic aid and also in small doses for the clinical appraisal of metabolic behaviour, radioisotopes appear to be well established with considerable potentialities The papers illustrate clearly that, in biochemical, physiological and agricultural research, radioisotope techniques have constituted a major advance in recent years for example, in the study of precursor–product relations in steady-state systems—an important problem scarcely soluble except by isotope tracer techniques Many useful and novel techniques are described for the location of radioisotopes in large animals, in plants, on paper chromatograms and in histological sections Some of the complications of radioisotope applications also receive attention, such as the difficulties of constructing directional counters, collimating powerful gamma-ray sources and the importance of recognizing radiation effects in labelled fertilizer studies

The standard of the papers is high for a conference of this sort, when sometimes papers are thinly disguised excuses for participation at a conference Surprisingly few typographical errors have been noticed Two papers mysteriously appear in the wrong section (pp 379 and 381), and the title "Chromatographic Techniques" includes a curious range of subjects The proceedings provide a unique review of recent developments in radioisotope applications not to be found in current text-books on the subject Moreover, they provide an indication of future developments, by whom and where, which is of particular value to the radioisotope specialist Although a more recent conference on radioisotope techniques was held in 1954, it seems unlikely to vitiate the value of the published proceedings of the 1951 conference F P W WINTERINGHAM

THE INTERNATIONAL GEOPHYSICAL YEAR, 1957–58

By PROF SYDNEY CHAPMAN, F R S

A DESCRIPTION was given in *Nature* of August 22, 1953, of the inception and progress of the plans for the world-wide enterprise entitled the International Geophysical Year. This is a successor to the two International Polar Years of 1882–83 and 1932–33 It follows the latter after twenty-five years, instead of the fifty that elapsed between the two Polar Years It covers the whole globe instead of being specifically devoted to the polar regions, and its scientific scope is far wider than that of its predecessors They fell near sunspot minimum , the International Geophysical Year will be at or near sunspot maximum, and its duration will be eighteen months, from July 1, 1957, to December 31, 1958

The International Council of Scientific Unions is the official sponsor of the enterprise, which it has adopted for the time being among its 'permanent services' , important financial support for the central organization is afforded also by the United Nations Educational, Scientific and Cultural Organization The Council has appointed a Special Committee to provide the central direction and co-ordination of the efforts of the many nations participating in the International Geophysical Year The Committee—known by the initials of its French title as CSAGI (Comité Spécial de l'Année Géophysique Internationale)—is constituted on a functional, not national, basis, being composed as follows of persons representing the international scientific bodies indicated (International Council) L V Berkner (vice-chairman), S Chapman (chairman), E Herbays and M Nicolet (general secretary , at 3 Avenue Circulaire, Uccle, Belgium) , (International Astronomical Union) A. Danjon and Sir Harold Spencer Jones, (International Union of Geodesy and Geophysics) J Coulomb, G. Laclavère, V Laursen and P Tardi , (International Union for Scientific Radio) W J. G Beynon and M Boella , (International Geographical Union) J M. Wordie, (International Union of Pure and Applied Physics) J A Simpson and S Vallarta , (World Meteorological Organization) J. Van Mieghem and T E W Schumann The Joint Commissions on Solar and Terrestrial Relationships, and on the Ionosphere, of the International Council are linked with the Special Committee through its members Nicolet and Beynon

The Special Committee held its first full meeting in Brussels in July 1953, together with some representatives of the national committees formed at the invitation of the International Council through Colonel E Herbays, the provisional secretary and convenor of the Committee, at its preliminary meeting in October 1952 At Brussels in 1953 the Special Committee considered reports and proposals from twenty-one national committees and from the Unions of Geodesy and Geophysics and of Astronomy, and from the World Meteorological Organization , these documents, and the agenda for the meeting, were published in the IUGG News Letter in its quarterly issue (Vol 2, Part 3) of July 1953. The proceedings, provisional programme and resolutions of the Special Committee, together with four additional national reports, appeared in the October 1953 issue of the News Letter This completed the first stage of the plans for the International Geophysical Year

The Special Committee held its second full meeting at Rome during September 30–October 4, 1954, in the palace (and by the courtesy) of the Italian National Research Council Between this and the 1953 meeting the national committees reviewed and developed their plans for the International Geophysical Year, in order to present revised reports to the Rome meeting The general secretary issued invitations to countries that had not yet decided to take part in the International Geophysical Year to participate in the enterprise, and to prepare plans in the light of the provisional programme drawn up in 1953 The associated international bodies represented on the Special Committee were also requested to give further consideration to the programme and plans They and the adhering nations were requested to send members to attend the Rome meeting to assist the Special Committee in its discussions. During the summer of 1954 meetings were held by the International Unions of Pure and Applied Physics, of Scientific Radio, and of Geodesy and Geophysics, as also by the Joint Commissions on the Ionosphere and on Radio Meteorology , at all these, active consideration was given to the plans for the International Geophysical Year

These intensive preparations bore good fruit Those attending the Rome meeting of the Special Committee numbered slightly more than a hundred, drawn from about thirty nations Almost all those present took an active part in the discussions of one or other of the many working groups which considered the various branches of the programme The documents resulting from the arduous labours of the first three days of the meetings (Thursday – Saturday) were prepared by the secretariat during the Sunday recess, and presented to a plenary meeting on October 4

At the outset of the meeting, the general secretary was able to report that thirty-six nations had formed national committees, and that the formation of others was pending During the meeting the officers were informed by the Embassy of the U S S R in Rome that the Academy of Sciences of the U S S R had responded to the invitations sent to it to participate in the International Geophysical Year, and had appointed a national committee for the purpose, under the presidency of Academician Gemburzev, director of the Geophysical Institute of the Academy , also that a U S S R delegation of eleven members, who as guests had attended the General Assembly of the International Union of Geodesy and Geophysics held in Rome during September 1954, had been appointed also to attend the meeting of the Special Committee Members of the delegation indicated that the U.S S R. Academy of Sciences would co-operate also in encouraging other nations to participate in the International Geophysical Year.

The principles so far tacitly applied in the selection of items for the programme of the International Geophysical Year were explicitly formulated at Rome as follows the first priority is given to problems requiring concurrent synoptic observations at many places on the globe, involving co-ordinated effort by many nations , second come geophysical problems the solution of which will be aided by the availability of the results of synoptic or other concentrated geophysical work undertaken during the Year , a third principle is that where the main programme involves the occupation of stations in regions of the earth to which comparatively little geophysical effort has been devoted, advantage should be taken of the opportunity to make observations also of other major geophysical phenomena, for example, earthquakes , fourthly, geodetic and other observations will be made of slowly varying geophysical phenomena, for comparison with similar future observations at later epochs

During the International Geophysical Year the most modern types of observation of many kinds, for example, meteorological, ionospheric, magnetic and auroral, will be more widespread over the globe, and made with greater frequency, than ever before. But even during this period there will be intervals of specially intensive observation. Definite plans have been formulated for the choice of these intervals, subject to final adoption by the Special Committee at its meeting in 1955 The intervals include three Regular World Days each month, of which two will be at new moon and one near the quarter moon , these have now been designated—they include days of predictable events such as solar eclipses and meteor showers. In the field of meteorology there will be six World Meteorological Intervals of ten days each, one in each period of three months, near equinox or solstice , each such interval includes the three Regular World Days during the month in which it occurs.

There are some geophysical phenomena, however, the occurrence of which cannot yet be predicted with much probability (if at all) more than a few days ahead, namely, magnetic and ionospheric storms and auroræ, which are dependent on solar flares and other exceptional events on the sun. Great magnetic storms are associated with the appearance of auroræ visible from regions far outside their usual limits—perhaps the most outstanding case was that of February 4, 1872, when a brilliant aurora was seen from the greater part of the globe, including Bombay and Aden It is hoped that if any such events occur during the Geophysical Year—and this may be expected—they will be properly observed, for the first time in geophysical history. Careful plans are being made to achieve this, and to enable ionospheric and magnetic observatories to give to such phenomena the special attention that is their due To this end there will be close co-operation between the solar observatories that will keep a close and (it is hoped) continuous watch on the sun, and the organizations that now make predictions of ionospheric and magnetic conditions , when the state of the sun indicates the likelihood of geophysical disturbance a few days ahead, a World Alert-Period will be designated, and notified the world over by radio and other means of communication When the continuing developments on the sun render it suitable, a Special World Interval will be declared about 12 hr in advance, to continue until terminated by the predicting agencies. The agencies will also give world-wide notice of the co mencement of great geophysical disturbances th may occur without having been foreseen. Throu these procedures it is hoped that detailed observatio of the morphology of these disturbances will possible, and that even down to low latitud preparations for proper auroral observation will made It is hoped that, in co-operation with centr elsewhere, the U.S. Central Radio Propagati Laboratory will undertake to designate and noti these special periods

The principal fields of geophysical science to cultivated during 1957–58 will be meteorology, ion spheric physics, geomagnetism, the aurora and a glow, and cosmic rays , astronomical institutio will give essential assistance through solar observati and their geodetic work on determinations of latitud and longitudes. Some effort will also be devoted oceanography, glaciology and seismology An portant programme of rocket observations has be formulated In this work the chief participant w be the United States , but it is hoped that some oth countries will also be able to arrange co-operation rocket studies of the upper atmosphere.

Careful attention was given at the Rome meeti to the geographical distribution of observing statio planned or desirable, in order to detect importa gaps, with the view of seeking means of filling the and also recommending combination or eliminati when unnecessary duplication might occur. Areas which special effort will be devoted are the Arct and Antarctic caps and the tropical zone, togeth with three special meridians, 70–80° W , 10° E a 140° E It appears that only minor changes in t programmes proposed by the various individu nations will suffice to achieve an excellent wor geophysical network

The measure of co-operation envisaged will, executed, make the International Geophysical Ye by far the most extensive and important inte national scientific enterprise yet accomplished

Gradually public knowledge of the plans for t International Geophysical Year is being spread newspaper and magazine articles in many countri The U S. Congress has made generous financial pr vision for the preliminary stages of American pa ticipation, which will be under the ægis of t National Scientific Foundation. President Eise hower, in a public statement, has warmly endors this far-reaching effort as one that will "ve materially strengthen our bonds with the ma co-operating nations and make a constructive co tribution to the solution of mutual problems". H Holiness Pope Pius XII has likewise commended t enterprise as one likely to contribute to a mo peaceful and co-operative attitude among t peoples of the world, as well as to their materi betterment

The countries participating in the Internation Geophysical Year, in alphabetical order according the English versions of the names of the countri are as follow (up to October 1, 1954) Argentin Australia, Austria, Belgium, Brazil, Britain, Canad Czechoslovakia, Denmark, Finland, France, Germa (Eastern), Germany (Western), Greece, Hollan Iceland, India, Ireland (Eire), Israel, Italy, Japa Mexico, Morocco, New Zealand, Norway, Pakista Peru, Philippines, Russia (U S.S R), South Afric Spain, Sweden, Switzerland, Tunis, United Stat (U S A), Yugoslavia

PRECISION ELECTRICAL MEASUREMENTS

A SYMPOSIUM having as its general theme the techniques of precision electrical measurement was held at the National Physical Laboratory during November 17–20. Twenty-six papers were read and discussed, the authors being drawn from a particularly wide field, including not only some of the principal electrical laboratories in Britain but also members of the national laboratories of Australia, South Africa and the United States, and well-known workers from Germany, Holland and Sweden. In opening the proceedings, Dr. P. Dunsheath remarked that precision is evidently used as a relative term, for the errors recognized in, say, some of the magnetic and high-voltage techniques would fill those dealing with more manageable techniques with horror. Indeed, the subsequent discussion showed that mere statements of percentage accuracy are seldom of much interest; the important points are those which ensure that an experiment does in fact satisfy the conditions postulated in asserting that the quantity measured is such-and-such.

The symposium was divided into five sessions which dealt successively with subjects that form substantial items in the work of the Electricity Division of the National Physical Laboratory and that bear more or less directly on industry. The first session was devoted to the techniques applicable to electric fields and dielectrics; the second to magnetic fields and associated materials; the third dealt with electrotechnical measurements; the fourth with standard techniques for the high-voltage laboratory; and the last with the techniques of impulse-testing.

Perhaps the most outstanding feature of the techniques for the measurement of dielectric constant and power loss discussed in the first session was the range of frequency covered. Various aspects of the standard bridge and resonance techniques were introduced by Dr. L. Hartshorn and E. Rushton and J. V. L. Parry, of the National Physical Laboratory. Dr. M. Gevers, of the Philips Research Laboratories at Eindhoven, emphasized the versatility of standing-wave methods for the microwave range, and it appears that these are superior to cavity resonator methods for materials of high loss, though the cavity has the advantage for low-loss materials. D. Woods, of the Ministry of Supply, showed that a bridge of the twin-*T* type can be constructed to give high precision at frequencies up to 300 Mc./s. At such frequencies, however, a massive block of brass used as the junction of two or more arms of the bridge is no longer an equipotential; it must be represented on the bridge diagram not as a mere junction point but as a network of small inductances. On paper, therefore, the bridge network opens out formidably, while the concrete reality shrinks to a closely interlocked group of brass blocks and cylinders the construction of which calls for mechanical work of very high precision. This indeed is a limitation of the technique, though its value for the particular purpose of calibrating standard coaxial components is obvious.

Considerable interest was also shown in techniques applicable to dielectric behaviour at extremely low frequencies. Dr. G. Mole and D. C. G. Smith, of the Electrical Research Association, described an a.c. bridge which is conveniently workable at frequencies down to 0.05 c./s., but the discussion showed that d.c. techniques are usually preferred for general work in this region, if only because, as C. G. Garton mentioned, time constants of the order of 50 hr. have been observed, and for periodic times of this order a.c. methods become quite impracticable.

Much of the discussion in the second session was concerned with various forms of permeameter used for determining the characteristics of industrial materials. C. E. Webb, of the National Physical Laboratory, dealt with standard methods for the delineation of magnetization curves. The discussion showed that the ballistic method is almost universally employed for the curves which serve as a basis for industrial design, and the discussion dealt largely with fine detail. Dr. M. McCaig, of the Permanent Magnet Association, stressed the difficulty of winding magnetic potentiometers with adequate uniformity and described a test that had revealed unsuspected errors in all such coils however carefully they had been wound. Prof. J. Greig and others mentioned the growing importance of methods for integrating and recording slow changes of flux and thus delineating individual cycles of magnetization, as a supplement to the ordinary curve for the steady cyclic condition that is determined point by point by the ballistic method; the two are clearly not necessarily the same and the differences are likely to be instructive. A paper by T. M. Palmer, of the Australian National Standards Laboratory, described a magnetometer in which a saturable core consisting of a short length of mumetal wire is used as a probe. The probe is small enough to serve as a null-detector for the measurement of *H* in a permeameter and it therefore offers an interesting alternative to search-coil methods; but its advantages have so far only been established for measurements of the earth's field and the like.

Methods for use at communication frequencies were described by A. C. Lynch, of the Post Office Engineering Research Station, and by P. H. Haas, of the U.S. National Bureau of Standards. Such methods depend on measurements of the inductance and equivalent resistance of toroidal cores provided with a suitable winding, the contribution of the winding alone being calculated or measured separately after removal of the core. The nature of the winding is an important factor; Mr. Haas places the core in a metal chamber which when closed by a cap forms a single short-circuited secondary turn; Mr. Lynch prefers a wire winding of three discrete turns; and Dr. C. M. van der Burgt, of the Philips Laboratories, showed an alternative scheme, by which a silver winding can be opened and closed for the insertion of the toroidal core, without introducing any uncertainty into the resistance of the winding, which is an extremely important factor.

A paper by R. L. Driscoll, of the U.S. National Bureau of Standards, described the determination at that laboratory of the magnetic moment of the proton (or more strictly its gyromagnetic ratio) by means of nuclear resonance. This brought microwave techniques and frequency measurement into the picture, and introduced the idea that the proton may conceivably serve as a magnetic standard accessible to everybody who can command the technique. The resonance frequency being determined only by the product of a constant characteristic of the proton and the field strength, it becomes possible to measure magnetic fields by observations of a frequency of resonance in water or any suitable material rich in protons used as a probe At the National Bureau of Standards the field is actually measured in present-day units by weighing the force on straight conductors of accurately determined length suspended in it The method is no doubt the best available for strong fields For weaker fields it is probable that greater accuracy could be obtained by producing the field by passing a measured current through a primary standard inductor The use of such an arrangement as a basis for magnetic measurements, and in particular for the calibration of search coils, was discussed in a paper by G H Rayner, of the National Physical Laboratory

The electrotechnical session began with the recognition that the accuracy of all measurements depends on the constancy of the quantities involved Two aspects of the underlying problem were discussed, namely, the constancy of a c generators and that of the alloys used for the construction of standard resistors It became clear that electronically stabilized supplies are coming into general use in standards laboratories, and the system described by B V. Hamon, of the Australian National Standards Laboratory, provided a good example , two 3-phase, 12 kVA. alternators have automatic control of both frequency and voltage to about 0 01 per cent at any setting in the working range C Petersen, of the U S National Bureau of Standards, reviewed the work on resistors, and great interest was shown in the subject It became evident that an alloy of exceptionally high resistivity and adequate stability has been sought in vain by many, that manganin still holds its place for stability, with constantan as an alternative that is almost indispensable for a c work, and that modified nickel–chromium alloys show promise of higher resistivity with stability The remaining papers centred around the problem of the d c to a c transfer standard In theory no standard is necessary , instantaneous values are measurable by direct reference to d c. standards, but practice is mainly concerned with steady-state values, and the accuracy required is much greater than can be obtained for instantaneous values Hence the importance of the stabilized supply mentioned earlier, and the transfer standard which indicates with precision either d c or stationary root mean square values Examples of the three types now in use were discussed a dynamometer wattmeter constructed by Dr O Brune and J W Whittaker at the National Physical Laboratory, South Africa , thermal instruments used as ammeters and voltmeters at the U S National Bureau of Standards described in a paper by F L Hermach , and the electrostatic wattmeter used at the National Physical Laboratory and described by Dr A H. M Arnold with particular reference to work at audio-frequencies

On proceeding to higher voltages, the same considerations apply with the additional complications that clearances must be made larger to avoid breakdown so that the equipment tends to become excessively bulky, resistors of extremely high value become necessary to avoid excessive power dissipation and transients as well as steady-state values are often required The compressed gas capacitor, discussed by Dr A Keller, of Hartmann and Braun A G , Germany, well illustrates one answer to the problem of keeping down the bulk of the equipment Single units containing carbon dioxide at 14 atmospheres pressure have now been made to withstand an operating voltage of 900 kV (r m s), with a capacitance of 65 pF They serve as standards fo the measurement of dielectric loss at high voltage G W Bowdler, of the National Physical Laboratory discussed methods for the measurement of hig voltages in steady-state conditions, especially th construction of resistors of high value, and potentia dividers, and the use of the attracted disk electrostatic voltmeter, which with compressed gas insulation has been used up to 600 kV. (peak). P R Howard, of the National Physical Laboratory, deal with the measurement of transients It is, of course the cathode-ray oscillograph that has made suc measurements possible, but accuracy depends largel on the proper control and assessment of stra capacitance and inductance in the auxiliary equipment of voltage divider and cables between th instrument and the point of the system unde investigation F S Edwards, of the Metropolitan Vickers Electrical Co , Ltd , discussed the sphere-ga as a peak voltmeter Most speakers saw somethin incongruous in the basing of a standard on anythin so erratic and violent as an electric spark , but th fact that standard calibrations for the sphere-ga have been issued in Britain, the United States an Germany is evidence of its practical importance fo the measurement of very high voltages and of th need for a knowledge of the ways of minimizing th errors and estimating their magnitude

The final session was devoted to a discussion o impulse tests on high-voltage equipment At first sight the problems are somewhat remote from precision measurement The objective is a proof o the ability of a transformer, cable or other insulated system to withstand surges of voltage such as are liable to arise in practice from lightning strokes o switching operations Surges of suitable severity must be generated, applied at specified points, and the currents or voltages at key points must then be examined for any departure from normal behaviou such as could arise from partial failure The whol problem is of such intricacy, including as it does th recognition and interpretation of special features i transients in complicated systems of inductance capacitance, etc , that the techniques are far les standardized than are those of a measurement However, the discussion showed that the technique have much in common with those of measurement The distribution of transients within a comple network, for example, is determined by facto exactly similar to those in a high-frequency bridge The problem of the common junction point in M Woods's bridge discussed in the first session has it counterpart in the common 'earth' of an impulse testing system, and the proper location of eart capacitance and residual inductance provides th solution in both cases The details, however, def summary treatment W G Standring, of th National Physical Laboratory, presented a genera survey of the problem , N Hylten-Cavallius, o A S E A , Sweden, an account of the design an construction of surge generators , G H Hickling, o C A Parsons and Co , Ltd , J Neuve-Eglise, o Electricité de France, and P G Provoost, o K E M A. Laboratories, Holland, each recorde experience of the detection of faults in transformers and B Salvage, of W T Henley's Telegraph Work Co , Ltd , discussed the corresponding problem fo cables and their accessories

The complete proceedings will be published as soo as practicable and will be obtainable from H M Stationery Office L HARTSHORN

BRITISH IRON AND STEEL RESEARCH ASSOCIATION

OPEN DAY AT THE BATTERSEA LABORATORIES

THE importance of both theoretical and applied research to the maintenance of Britain's industrial position is being increasingly recognized to-day, and the iron and steel industry, which can fairly be described as the core of the entire British industrial complex, is particularly conscious of the vital bearing of research on economic efficiency. The extensive facilities of many industrial firms were further reinforced by the formation in 1945 of the British Iron and Steel Research Association. Besides laboratories at Sheffield, Normanby and Swansea, where practical problems can be tackled in the heart of the appropriate industrial centre, much theoretical and supporting work is carried out by the London laboratories of the Association, notably those at Battersea. Something of this work, chiefly that of the Plant Engineering Division and the Physics and Chemistry Departments, was on view on November 18 and 19, when there were open days at the laboratories. Besides fundamental research into their own special subjects, the groups concerned support the general work of the Association's other Divisions. The short notes which follow give a brief survey of a selection of these projects illustrated at Battersea.

Plant Engineering. The Electrical Engineering Section of the Plant Engineering Division has recently been studying the relation of the operator to his working environment in an attempt to match the control to his abilities, thus achieving a higher working efficiency for the manually controlled machine. The work arose out of earlier crane studies which showed that controls were often badly arranged, difficult to manipulate quickly, and lacking in realism—that is, handles did not move in the direction of motion. Re-design of the master controller itself allowed a much more compact grouping of the controls around the operator, and provision of a work seat designed by Dr. H. Darcus, of the Department of Anatomy, University of Oxford, helped to improve the operator's working conditions. Attention was then turned to the design of the crane cab itself, with the result that visibility was much improved. As a result of this first phase of the work, a series of suggestions were published[1], many of them quantitative, on the design of controllers and control points in steelworks.

In 1953 a Mutual Security Aid grant was obtained to continue and extend this work. Attention has been given to the design of foot controllers, about which little is known, and which have great potential value where several controls have to be operated by one man. Experimental equipment has been designed consisting of one of the new controllers equipped with an adjustable foot-pedal and connected to a motor driving a visible jockey. Several operators were trained to move this jockey via the foot control, so as to make it coincide with a hand-set jockey, and were then given tasks of adjusting the device to different set points for a given period each day. All foot movements were recorded on teleprinter tape, and subsequent analysis has enabled the best position of the foot-pedal pivot, relative to the ankle point, to be determined approximately. This work is being continued, and it is proposed also to compare the relative merits of pivoting and 'push' type foot controllers.

Quite wide divergencies still exist in hand controllers in the angle of movement, spacing of steps, length of handle, force required to operate the handle, and type of handle grip. In an attempt to determine the optimum conditions, a special controller has been made in which these factors can be varied. Here again, the operators' success in controlling a jockey with the hand controller will be measured and will form the criterion by which the quality of the control will be assessed.

Chemistry Department. The presence of nitrogen is a contributory factor in the development of ageing phenomena and in causing poor magnetic qualities in silicon–iron transformer sheets. Alloying elements can overcome these effects in some degree by encouraging the formation and precipitation of free nitrides from the solid solution of nitrogen in iron. The problem centres, therefore, on a more exact knowledge of the effect of these alloys and the conditions under which free nitride phases can be formed. Experiments are in progress in which alloy steels are progressively nitrided at various temperatures in order to discover when nitride phases are produced.

The Refractories Section is investigating the composition and performance of lining materials. Very little is known about the influence of mechanical and flow properties of basic bricks, particularly when heavily contaminated, on their behaviour in a furnace roof. Measurements of crushing-strength are being made at temperatures up to 1,100° C. on specimens cut from used bricks. At this temperature the materials still behave elastically. In addition, a study is being made of the plastic properties at higher temperatures under different rates of strain corresponding to various rates of bursting expansion or lateral compression.

The Corrosion Section exhibited many specimens from field trials of various methods used for protecting iron and steel from corrosion in the atmosphere, in salt water, and in soil. An interesting piece of equipment is the rotor test apparatus which has been built to facilitate laboratory study of the corrosion factor in iron and steel exposed to flowing water. The liquid medium can, of course, be varied, and different natural conditions can be reproduced as the investigation requires. By rotating the specimens at speeds up to 15 knots, the effect of corrosion on moving ferrous objects—such as ships' hulls—can be simulated. The flowing liquid also substantially speeds up the onset of corrosion, a factor of some importance in facilitating investigations.

Physics Department. Two important advances have been made in steelmaking processes as a direct result of research work in the Physics Department. The continuous casting of steel has long been recognized all over the world as likely to have considerable economic advantages over conventional ingot casting. Research has been carried out for the past few years in the London laboratories, and its outcome is an experimental production plant, which began operation in April 1954, for the continuous casting of special steels in a member's works. This is the first two-strand plant ever to be operated by the British steel industry, and it provides a very good example of co-operation between a research association and its industry. Eleven interested companies have formed a development group to finance the capital and running costs of the continuous casting installation

A second advance has been the development of a new burner for oil or oil and coke-oven gas used in open-hearth furnaces. A study of existing burners in which the fuel was atomized at the back end of the burner showed that a high proportion of the input energy was being wasted. Measurements of the momentum-producing efficiency showed that it was better to dispense with back-end atomizers, and to allow liquid fuel to be accelerated gradually towards the burner tip where atomization occurs. The Association's burner is thus very simple to construct. Trials on several open-hearth furnaces carried out jointly by the staff of member firms and the Association have shown very important improvements in increased productivity, longer furnace-roof life, a more efficient use of steam, and the lower cost of fuel per ton of steel produced[1].

The cleaning of industrial gas and fume is a topic of enormous national importance, and the Department is preparing to play an increasing part in the study of this problem. Fundamental work in 'particle capture' has shown that to be effective the water must be in droplets comparable in size to the dust particles, and the essential weakness of the existing spray method lies in the great variation in size of the droplets produced. An experimental unit was therefore devised incorporating spinning disks, in which the gas passes through an annulus surrounding five disks on a common shaft, rotating at speeds up to 5,000 r.p.m. The gas then passes through a bank of irrigated cyclones to remove the water droplets carried forward. For particles 1–76 μ in diameter, overall efficiencies exceed 98 per cent, but this falls to about 60 per cent for particles less than 1 μ in diameter. Further work is being carried out to improve this performance.

Dust-laden gases from many industrial processes are being studied, and valuable data are being accumulated. This will help in selecting suitable plant for specific conditions, and in estimating the efficiency of various types of cleaning plant.

THE NEW MEGAVOLTAGE RADIOTHERAPY UNIT AT MANCHESTER

THE Christie Hospital and Holt Radium Institute, Manchester, the largest radiotherapy centre in the world, has recently received important additions to its X-ray equipment, in the form of a 4-million volt linear accelerator and a 20-million volt betatron. Both machines were made by the Metropolitan-Vickers Electrical Co., Ltd., at Trafford Park, Manchester, the former being purchased by the Ministry of Health as part of a plan to equip key radiotherapy centres with this type of apparatus. The betatron is the gift of the makers to the Christie Hospital.

The machines are housed in a specially designed building, provided by the Medical Research Council, which is also financing the work to be done with them. This building provides the usual patients' waiting rooms, examination rooms and medical offices, and also a workshop, photographic dark-room and a number of laboratories. Some of these will be used by the physicists attached to the department, while others can be occupied by teams from the main research laboratories of the Christie Hospital, when they are working with the megavoltage radiations. Since it will be necessary to compare the effects of the high-energy radiations with those of the familiar 'deep therapy' range (200–300 kV.), the new department also has a 300-kV. 'Resomax' X-ray tube for this comparison work.

The linear accelerator is of the travelling wave type[1], in which electrons are accelerated by 'surf-riding' on radio waves, the speed of which increases down a corrugated wave-guide. For the acceleration of electrons to an energy of 4 MeV. a tube of only 1 metre long is needed, and this can be mounted on a single-ended gantry-type of mounting (Fig. 1), which can be swung about a horizontal axis, so that the X-ray beam can be aimed in any direction from 15° beyond the downward vertical to 15° beyond the horizontal (a total swing of 120°). Collimation of the beam is by means of adjustable diaphragms of lead, lined with tungsten 'heavy' alloy; treatment fields (at 1 metre) varying from 4 cm. × 4 cm. up to 25 cm. × 30 cm. can be obtained. Circular fields are obtained by inserting lead blocks, pierced by conical holes, between the jaws of the collimator. Since for megavoltage radiations the intensity falls off rapidly on either side of the central axis of the beam, a conically-shaped filter has to be used to produce a uniform field of irradiation. Under such conditions, dose-rates up to 200 r. per min. at a metre from the target can be obtained.

In the betatron[2], the first of its kind to be used in Britain for medical purposes, electrons are accelerated as they circle around inside a magnetic field which is increasing sinusoidally. The electrons reach their maximum energy in 1/600 sec., in which time they have travelled some 300 miles, gaining 80 eV. of energy on each of their 250,000 revolutions around the magnetic field. The magnet, which weighs 7½ tons, and the acceleration vessel or 'doughnut', are mounted so that they can rotate through an angle of 120° about a horizontal axis (Fig. 2). Thus the X-ray beam can be fired in any direction from 15° above the horizontal to 15° beyond the vertical downwards. In addition, the framework carrying the magnet can be raised or lowered through a distance of 7 ft., so that the machine has all the freedom of movement required for radiotherapy.

The collimation of the beam in this machine is by means of cylinders pierced by suitable conical holes, inserted through the lead protective wall placed in front of the doughnut. So that these cylinders shall not have eddy currents induced in them by the changing magnetic field, and yet provide adequate radiation shielding, they are made of a mixture of lead shot and litharge. Each will carry its own compensating filter to give a uniform intensity of radiation across the treatment area.

The beam at 20 MeV. is even narrower than at 4 MeV., and therefore the maximum field reasonably attainable is much smaller than with the linear accelerator, and is a circle of 13 cm. diameter at 1 metre. With the compensating filter in position, the betatron delivers about 50 r. per min. at a metre from the target.

Though these new machines will be used in the Hospital's main research programme into the action of radiations on living tissue, and though the irradiation of biological materials will serve as an invaluable aid in deciding correct dosage for the treatment of patients, the main function of the new equipment is the treatment of cancer.

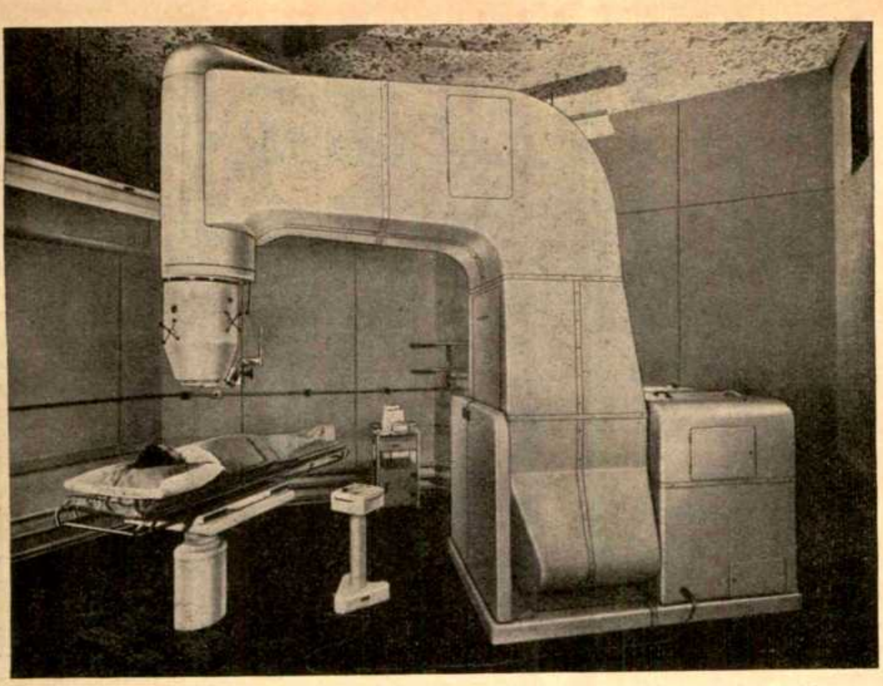

Fig. 1. Metropolitan-Vickers 4-MeV. linear accelerator with X-ray beam in vertical position

In radiotherapy, it is often necessary to treat a cancer growing deep in the body. To do this an adequate dose of radiation must be delivered to the tumour area without overdosing other parts of the body. This is usually achieved by using a number of X-ray beams aimed at the tumour from different directions. The more penetrating the X-rays, the fewer the number of beams that have to be used, or the smaller the dose which each beam has to give to the normal tissue through which it passes.

Since the penetrating power of a beam depends on the voltage used for its generation, the first advantage offered by megavoltage radiations is increased penetrating power, and hence the ability to treat deep tumours much more efficiently. The radiations, however, have other considerable advantages. One is that they are less scattered than are lower-energy rays, and thus the amount of radiation received by tissues outside the geometric confines of the beams is greatly reduced. Another advantage arises from the behaviour of the electrons set in motion by the attenuation of the X-ray beam in the material through which it passes and which are responsible for most of the effects of the radiation. These travel predominantly forward in the direction of the beam, and, giving up most of their energy at the end of their track, produce the highest dose some distance below the surface. For 4-million volt X-rays, the maximum is about 1 cm. below the surface, while for 20-million volt X-rays it is as much as 4 cm. deep. With these radiations, therefore, the effect on the skin is greatly reduced and skin reactions, so troublesome at 250 kV., are practically eliminated. A further advantage arises from the fact that scattering, which depends but little on atomic number, is the predominant mechanism by which the beam is attenuated at these energies, and thus the absorption of the rays in bone and in soft tissues is much more nearly equal than it is at lower voltages. Therefore there is far less danger of overdosing bones and of underdosing, because of the shadow effect, tissues which lie beyond bone.

While these physical advantages are firmly established, the biological effects of the megavoltage radiations are not so certain. It appears likely that they will be similar to those produced by the familiar 250-kV. range of X-rays, but this is not certain. Some biological effects are dependent on the linear ion density of the radiation, and since this is smaller for megavoltage radiation than for 250 kV., this may have some influence. Further, both machines produce

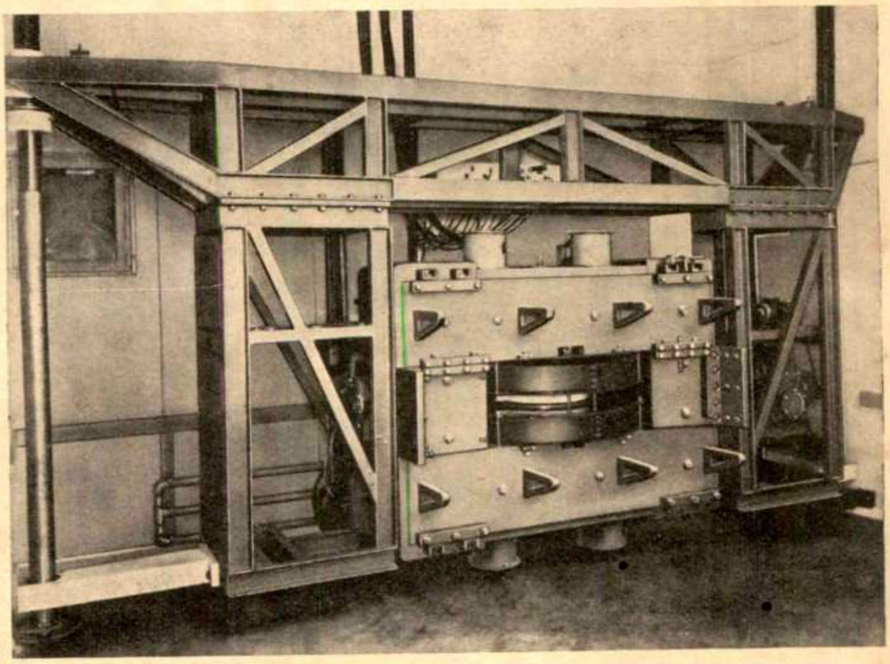

Fig. 2. Metropolitan-Vickers 20-MeV. betatron during installation

radiation in pulses of very short duration, and hence of high instantaneous dose-rate instead of the approximately uniform dose-rate of the conventional equipment, and this again may cause differences. The evidence so far available, in fact, suggests that the high-energy X-rays are slightly less efficient than lower-energy ones in producing some biological effects. Therefore clinical work with the two machines is going forward very cautiously, supported and guided by the results of comparison experiments using various biological and chemical indicators.

It must be stressed that the new machines do not offer any prospect of miraculous cancer cures; but it is confidently hoped that they will increase the proportion of cures already being attained with lower-voltage apparatus. Of one thing there can be no doubt: this unit offers unique opportunities for the study of the effects of ionizing radiations in malignant diseases.

OBITUARY

Prof. G. H. Shull

The death occurred recently of Prof. George Harrison Shull. He was born in Clark County, Ohio, in 1874. After taking his B.S. degree at Antioch College he graduated Ph.D. at Chicago in 1904. His first post was that of student assistant at the United States Department of Agriculture, Bureau of Forestry. After this he was successively botanical assistant a the U.S. National Museum, assistant plant physiologist at Chicago, and botanical investigator a the Carnegie Institution of Washington, where he remained for eleven years. In 1915 he became professor of genetics at Princeton University, where he worked until his retirement in 1942.

Prof. Shull is principally known for his pionee work on pure lines in maize, which laid the foundations of the huge hybrid-maize industry of the United States, based on the crossing of lines which had been inbred for long periods. But throughout his long and productive scientific career he worked extensively on a variety of topics. He concerned himself, among other things, with the heredity of sex in *Melandrium*, linkage and mutation in *Oenothera* and with self-incompatibility in *Capsella*.

Many academic honours were conferred on Shull including honorary doctorates from Lawrence College and Iowa State University. He was a member of, and took an active part in, the administration of the Genetics Society, the Eugenics Research Association the Philosophical Society, and the Torrey Botanica Club, of which he was president in 1947.

Prof. Shull was among the few remaining workers in genetics who date back to the early years of Mendelism. A final word must be said about one of his most noteworthy characteristics. He devoted much time and thought to young workers and was always ready to draw on his vast knowledge and experience for their guidance. A simple, kindly and serene man, he will be much missed.

S. C. Harland

NEWS and VIEWS

New Year Honours

The following names of scientists and others associated with scientific work appear in the New Year Honours list:

Baron: Dr. E. D. Adrian, president of the Royal Society and also of the British Association.

K.B.E.: Sir John Stopford, vice-chancellor, University of Manchester; Dr. Owen H. Wansborough-Jones, chief scientist, Ministry of Supply.

Knights: Prof. Wilfrid E. Le Gros Clark, Dr. Lee's professor of anatomy in the University of Oxford; Prof. Leybourne S. P. Davidson, professor of medicine in the University of Edinburgh, and president of the Royal College of Physicians of Edinburgh; Dr. Keith A. H. Murray, chairman of the University Grants Committee; Dr. Oliver G. Sutton, director of the Meteorological Office (Air Ministry) and president of the Royal Meteorological Society.

C.B.: G. R. D. Hogg, Under-Secretary, Department of Scientific and Industrial Research.

C.M.G.: D. M. Balme, principal of University College, Gold Coast; B. A. Cash-Reed, attaché for food and agriculture at the British Embassy in Washington; Dr. R. Lewthwaite, director of Colonial Medical Research; Prof. W. L. Waterhouse, lately professor of agriculture in the University of Sydney, for services to the wheat industry in Australia; T. Y. Watson, Secretary for Agriculture and Natural Resources, Uganda.

C.B.E.: C. E. J. Biggs, director of agriculture, Tanganyika; C. S. Bryant, lately director of materials and explosives research and development, Ministry of Supply; Dr. C. J. Gadd, keeper, Department of Egyptian and Assyrian Antiquities, British Museum; Dr. M. W. Goldblatt, director, Industrial Hygiene Research Laboratories, Imperial Chemical Industries, Ltd.; Dr. A. W. Greenwood, director, Poultry Research Centre, Edinburgh (Agricultural Research Council); W. F. Grimes, director, London Museum; G. W. Lines, director of agriculture, Sierra Leone; P. McNee, director, Drainage and Irrigation Department, Federation of Malaya; Prof. R. Peers, emeritus professor of adult education in the University of Nottingham, chairman of the Central Committee for Adult Education in H.M. Forces; Miss Audrey I. Richards, director, East African Institute of Social Research, Makerere College, Uganda; F. S. Russell, secretary of the Marine Biological Association of the United Kingdom, and director of the Plymouth Laboratory of the Association; E. E. Shipton, explorer and mountaineer; Prof. C. H. Smith, professor of instrument technology in the Royal Military College of Science; Dr. E. L. Taylor, deputy director, Veterinary Laboratories, Ministry of Agriculture and Fisheries; Prof. G. F. J. Temple, Sedleian professor of Natural Philosophy in the University of Oxford; L. C. Wilcher, principal of the University College of Khartoum, Sudan; J. Wright, director of agriculture, Jamaica.

Instrument Technology in the Imperial College, London: Prof. J. D. McGee

The recent announcement that Dr. J. D. McGee had been appointed by the University of London to the University chair of instrument technology provides an interesting example of the expanding activities of the Imperial College of Science and Technology At an earlier period of its history, nstrumentation had been represented there by the chair of instrument design held by the late Prof A. F C. Pollard, but on his retirement no successor was appointed Prof McGee's particular interests ie in the field of photoelectric, electronic and television techniques rather than in the mechanical design of instruments, and as head of the new post-graduate Section of Instrument Technology in the College, he will be responsible for the development and application of these and similar devices to physical problems

Educated at the University of Sydney, and awarded in 1928 an 1851 Exhibition travelling scholarship, he worked for three years under Lord Rutherford at the Cavendish Laboratory From there, he went to the research laboratories of Electric and Musical Industries, Ltd, where he first worked on the development of high-vacuum cathode-ray tubes for television picture reception and later directed the research group which had been given the task of developing the pick-up tubes used in television cameras During the War he was especially concerned with infra-red image converter tubes, not only with their development in the laboratory, but also with their factory production and with their military application After the War, Prof McGee was in charge of the group at Electric and Musical Industries, Ltd, responsible for striking developments in television camera pick-up tubes, charge storage tubes and photoelectric electron multipliers These techniques are likely to be exploited to great advantage in the new Instrument Technology Section of the College A staff of wide experience is being recruited and will help to establish a senior school of instrument technology that can be expected to make major advanced contributions to science and ndustry

Jacques Dubois (Jacobus Sylvius) (1478–1555)

JACQUES DUBOIS, who died in Paris four centuries ago on January 13, 1555, was a humanist who made many original contributions to anatomy and helped to reform its teaching. The son of a weaver, he was born in 1478 at Louville near Amiens, from which town he derived his Latin cognomen Jacobus Sylvius Ambianus As a student at the college of Tournay near Paris, he excelled in Latin, Greek, Hebrew and mathematics, invented machines for transporting water and wrote a popular French grammar After studying medicine in Paris, he travelled widely to mprove his knowledge of pharmacy Despite his ack of a degree, which he was too poor to obtain, his success as a teacher was so great that the Paris medical faculty stopped his courses because they nterfered with the regular schools. Sylvius then went to Montpellier, where he graduated in medicine on June 28, 1531, and on his return to Paris taught anatomy at the Collège de Tréguier, insisting that this subject can only be studied from the human body by eye and touch, and not by reading and description Though he often followed Galen blindly, he succeeded in clarifying many of the garrulous and obscure passages He frequently had five hundred pupils, who included Vesalius, Servetus, Conrad Gesner and Charles Estienne He gave specific names, some of which are still in use, to the muscles which Galen had designated by numbers, described the valves in the veins, and the sphenoid bone, and was a pioneer in practising the art of injection At the age of seventy-two he was appointed professor of surgery at the Royal College of Paris The aqueduct and the fissure of Sylvius were described by another Sylvius (François de la Boe) a century later

Zoological Society and B B.C. Expedition to West Africa

THE expedition organized jointly by the Zoological Society of London and the British Broadcasting Corporation returned to Britain just before Christmas from ten weeks field-work in Sierra Leone, bringing a large collection of animals and a considerable quantity of cinematograph films and sound recordings. The animals are for the Society's collection at Regent's Park, London, and the films and recordings are for the B B C's television service—some programmes have already been broadcast One of the main objects of the expedition was to find the nesting habitat of *Picathartes gymnocephala,* a rare passerine bird the systematic position of which is obscure; this bird has seldom been seen alive by Europeans. The habitat was found in difficult hilly bush country, and in spite of the dense shade cast by the forest successful films were made of the birds on and near the nests, of the eggs and of the parents feeding the young by regurgitation Sound records were also obtained of the voices of the birds in their natural surroundings, and a living specimen was captured and brought to London Another species never before exhibited in captivity that was successfully sought and found is the brilliantly iridescent emerald starling *Coccycolius iris* Small flocks of this bird were discovered in the open savannah country of the highlands in the north near the French border Much interesting film was made of various invertebrates, including several species of ants such as the driver, fire and Matabele ants, mantids, nest-building Hymenoptera and termites, as well as many subjects among the vertebrates A further series is of particular anthropological interest as it shows some of the ritual dances used in connexion with the initiation ceremonies of the secret societies that have such a powerful influence over the lives of the pagan natives Lengthy sound-recordings of the music and songs accompanying these dances were also made The Zoological Society and the B B C hope that the results of this joint venture will justify the organization of further field-expeditions to other parts of the world in the future

Pool of Spraying and Dusting Equipment

A POOL of spraying and dusting machinery for use in the Colonial territories is being established by the Colonial Office, in co-operation with the Imperial College of Science and Technology and the machinery manufacturers, at the Imperial College of Science and Technology Field Station, Silwood Park, Sunninghill, Berks Manufacturers of spraying and dusting machinery have been approached through the Agricultural Engineers Association and are co-operating in the establishment of the pool by the loan of suitable equipment The College has for some years maintained a representative collection of spraying and dusting machinery for teaching and experimental purposes, and this collection will be incorporated into the pool, which will include equipment designed for agricultural, stored products and public health work The pool will fulfil three purposes (1) the instruction of students (especially students preparing to undertake work in the Colonies) of agriculture, entomology, mycology, etc , in the different types of equipment, their use and maintenance , (2) the demonstration of the equipment to interested potential users in the Colonies , (3) the consideration of modifications to machinery to meet special conditions of tropical use A comprehensive reference library of spraying- and dusting-machinery manufacturers' literature is to be formed for the use of visitors A committee on which the Colonial Office, the Imperial College, and the Agricultural Engineers' Association are represented has been set up and is responsible for the running of the pool and for the selection of machinery offered by any manufacturers for inclusion in the pool Mr A E H Higgins, Imperial College of Science and Technology, London, S W.7, is in charge of the pool

Hilger Journal

The first number of the *Hilger Journal*, published in November 1954, is an illustrated pamphlet of eight pages of which approximately one-quarter is devoted to abstracts of recently published papers on spectroscopy. The issue contains also an account of the Hilger equipment installed in the new research laboratories of the Quasic Arc Company, Bilston, Staffordshire, and an extract concerning the use of optical methods from a talk by Dr J Haslam, of the Plastic Division of Imperial Chemical Industries, Ltd , on physical methods in the analysis of plastic materials With regard to a new and complete direct–direct spectrograph, known as a polychromator, the merits and demerits of the two main systems of spectrochemical analysis, photographic and direct reading, are explained. A special Schwarz thermopile which can be used as a replacement in certain types (not Hilger) of infra-red spectrometers has been designed and details of its application are to be studied , but meanwhile a preliminary catalogue description has been prepared and is available on request from Hilger and Watts, Ltd , 98 St Pancras Way, London, N W 1

Central Leather Research Institute, India News Bulletin

The Central Leather Research Institute, which was opened in Madras in 1953, is one of a chain of twelve National Research Institutes established by the Government of India under the ægis of the Council of Scientific and Industrial Research The scope of its work is to "carry out research in all aspects of leather industry, to solve problems which confront particularly the Indian leather industry and also to contribute to the international leather research which is being directed to extend leather science". It has now issued its first monthly bulletin (1, No 1 , August 1954 , pp 26 From the Institute, Adyar, Madras-20. Annual subscription Rs 9 or 18*s* , single issues Rs 12) It is stated that each bulletin will contain abstracts, research papers of the Institute, other articles on leather technology and trade advertisements In this issue, there are two articles The first deals with "Some Aspects of Leather Manufacture" and is by Prof B M Das, a recognized authority of long standing. Reference is made to the work of the Institute on the use of native barks to replace imported wattle extract, the presence of different tannins in avaram bark, rapid sole-leather tannages, new syntans from Indian coal-tar distillation products, basic aluminium salts in spray-dried powder form and tanning agents from mineral oil The second article describes the improvement of the tanning properties of mangrove liquors by modification of their acid and salt contents Th bulletin is well produced and of considerable interes in Britain, because the Institute seeks to improve th quality of the raw and crust-tanned hides and skin exported to this country

Insecticide and Repellent Action of Certai Chemicals

A handbook giving the results of tests of insecticidal action and repellency on fifteen species o insects and arachnids of medical importance ha been compiled by W V King, of the Agricultura Service of the United States Department of Agriculture, and published as Agriculture Handboo No 69 under the title of "Chemicals evaluated a Insecticides and Repellents at Orlando, Fla" (p 397 Washington, D C Govt Printing Office, 1954 2 25 dollars) Eleven thousand chemicals were included in the tests, each chemical being graded int one of four or five categories according to its efficiency A brief description of the methods of testing is give The results give some indication whether or not th chemical tested had marked insecticidal or repellen properties to the particular species of insect on whic it was tested , but, in the absence of any informatio on the reproducibility and degree of variation of th results, it does not seem possible to assess whethe the difference between the categories listed is reall significant A critical study of the test method employed would add greatly to the value of th results It is stated that the data are presented i the belief that they may prove useful to worke engaged in the development of new insecticides or i the study of the relation of chemical structure t insecticidal activity, 'and this may well prove t be so.

Medicine in the Atomic Age

The November issue of *Medicine Illustrated* co sists of a number of articles under two gener headings peaceful uses of atomic energy , an atomic warfare, medical aspects Prof J Rotbl describes with admirable clarity for the layman th nature and production of radioisotopes, and Mr Veall has the hard task of selecting examples of ho these isotopes are used in investigation and diagnos Drs R Bodley Scott and R M Cunningham a clear in describing the uses of phosphorus-32 an iodine-131 for therapy, and Dr R J Walton surve the therapeutic uses of other radionuclides Mr Dunster, as a health physicist, explains how person protection is achieved and how contaminated was can be disposed of Prof. K. Mather ends a go collection of papers with an admirable survey of t genetical price of radiation On the medical aspec of atomic warfare, the authors are on a mu 'stickier wicket' and, like the most skilled performe in such conditions, are guilty of many lapses fro orthodoxy However, few would dare to predict t future in this field, so that in general any stimul to thought is good. From an illustrated journal o would have expected more pictures and less scri and surprisingly many of the illustrations are ve poor , by far and away the best is an abstract fro a case report by L H Hemplemann with colour plates from *Medical Radiography and Photography*

Aerosurvey by Photography

Mr. A. D. Dodds-Parker, Parliamentary Und Secretary of State for Commonwealth Relations, w open an exhibition of photography in aerial survey work at the Kodak Gallery, 184 Regent Street, London, W 1, on January 10 The exhibition shows something of the activities of Hunting Aerosurveys, Ltd , Hunting Geophysics, Ltd , and Aerofilms, Ltd Hunting Aerosurveys, Ltd , are concerned mainly with stereoscopic photography for map-making , Hunting Geophysics, Ltd , engage in mineral prospecting , and Aerofilms, Ltd , specialize in 'oblique' shots of towns, well-known land-marks and industrial projects The exhibition will be open to the public during January 11–29 (Mondays to Fridays, 9 30 a m –5 p m , Saturdays, 9 30–11 30 a m), admission is free.

University of London : Appointments

The following appointments in the University of London have been announced Mr. G A Barnard, reader in mathematical statistics in the Imperial College of Science and Technology, to the University chair of statistics tenable at that College , Prof Arnold Tustin, professor of electrical engineering in the University of Birmingham, to the University chair of heavy electrical engineering tenable at the Imperial College of Science and Technology , Dr Paul Fatt, senior research fellow in physiology at the Australian National University, Canberra, to the University readership in biophysics tenable at University College The title of professor of zoology in the University has been conferred on Dr G P. Wells in respect of his post at University College, London.

University of London : Awards

The following awards made by the University of London have been announced *I C I Fellowships*, each of the value of £750 per annum, and tenable in the first instance for three years D R Bland, for research in theoretical mechanics, in particular in plasticity and heat transfer, at the Imperial College of Science and Technology , Dr G W H Cheeseman, for research on the chemistry of organic nitrites and nitrates, at Queen Elizabeth College , Dr G. L Sewell, for research on the fundamental theory of condensed matter, at the Imperial College of Science and Technology , Dr G H A Cole, for research in the field of ionic physics, at University College , Dr R. Pettit, for a study of conjugated organic molecules containing one or more hetero atoms, at Queen Mary College , *Turner and Newall Research Fellowship*, of the value of £750 per annum, and tenable in the first instance for three years, to Dr. T J Lewis, for research on the electrical strength of pure liquids, at Queen Mary College.

Announcements

Prof Robert Cruickshank, professor of bacteriology in St Mary's Hospital Medical School, London, has been appointed principal of the Wright–Fleming Institute of Microbiology at the School in succession to Sir Alexander Fleming, who has retired.

Dr Reginald Child has been appointed director of the Tea Research Institute of East Africa in succession to Dr T Eden, who retired in June Dr Child has been senior chemist of the Institute since its inception in 1951 (see *Nature*, 169, 959 , 1952).

The Thomas Young Oration for 1955 of the Physical Society will be delivered by Dr W S Stiles (National Physical Laboratory) on February 25, in the lecture theatre, Science Museum, London, S W 7, at 5 p m , Dr Stiles will speak on "The Basic Data of Colour-matching and Some Related Aspects of Visual Theory"

The spring meeting of the Physical Society will be held at the Atomic Energy Research Establishment, Harwell, during March 31–April 2 The subject of the meeting will be "Neutron Physics and Energy Levels" Accommodation can be arranged at Lincoln College, Oxford, provided notification is received at A E R E, Harwell, not later than January 31 Application forms to attend the meeting can be obtained from the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S W 7

A pamphlet on selenium, by R Ashton, E G Hill and D Neville-Jones (London H.M S O , 1*s* 6*d* net), gives a concise but very informative survey of the sources, production and uses of selenium, and includes the use of selenium in the glass industry and selenium rectifiers (as an alternative to germanium) There is at present a shortage of selenium, and possible alternatives are discussed

A technical data sheet, of thirty-four pages, on piperidine has been issued by Robinson Bros , Ltd , of Ryders Green, West Bromwich, Staffs It contains a survey of the physical and chemical properties of piperidine and descriptions of reactions in which it is used, with complete references to the literature, and is likely to be of service in chemical laboratories In addition to pure piperidine, the commercial varieties are considered. The document is very useful in that it contains information not otherwise easily available.

A symposium on "The Protection of Structural Steel", organized by the Corrosion Group of the Society of Chemical Industry, will be held in London in the lecture theatre of the Institution of Civil Engineers during March 31–April 1 Those contributing papers will be from Belgium, France, Holland, Sweden and the United States, as well as Great Britain, and accounts will be given of practical experience and of research with protective coatings Further information can be obtained from the honorary secretary of the Group, S C Britton, Tin Research Institute, Fraser Road, Perivale, Greenford, Middlesex

A series of seven lectures on "The Shape of Work to Come" is being given at St Anne's House, Soho, on Thursdays at 6 30 p m , beginning January 13. The speakers will include the Right Hon. L J Edwards, on the philosophy of work , Mr J R Gass (Intelligence Division, Department of Scientific and Industrial Research), on the implications of automatic production , Dr R W Revans (formerly director of education, National Coal Board), on the scale and structure of industry , Mr A Healey (British Institute of Management), on the significance of industrial psychology and welfare , Dr M. M Fmiston (Atomic Energy Research Establishment, Harwell), on the transformation of society by the coming of atomic power , Prof Michael P Fogarty (professor of industrial relations, University of Wales), on the true end of man and his work Admission is by ticket only, obtainable from the Secretary, St Anne's House, 57 Dean Street, Shaftesbury Avenue, London, W 1 , single lectures, 2*s* (house members 1*s* 6*d*), season tickets, 12*s*. 6*d*. (house members 10*s*)

RESEARCH AND INDUSTRIAL PRODUCTIVITY

DURING November 22–25, the Department of Scientific and Industrial Research, in association with the British Productivity Council, held a working conference on "Research and Industrial Productivity" At its opening luncheon, the Lord President of the Council, Lord Salisbury, stated the national problem, that unless we can work to better advantage, making full use of the knowledge which science can provide, Britain will be unable to maintain its social services and exercise its proper influence in world affairs The conference itself was directed both to the considerations which determine whether and how quickly a scientific or technological advance can be successfully introduced into industry, and also to the scientific studies by which management and work can be improved so as to yield a higher productivity The British Productivity Council and many industrial leaders participated, but the body of the conference came mainly from the councils and staffs of research associations, nationalized industries, and a few from government departments.

At the first session, Sir Ben Lockspeiser recalled that King George V, when Prince of Wales, had described the problem in opening the National Physical Laboratory half a century ago Since then, Sir Ben said, we have developed a greater social conscience and Britain's share in world trade has diminished To maintain and increase our living standards we must both expand our production and increase its efficiency We must particularly seek increased efficiency with a minimum of capital investment, because this is a charge on productivity Similar economy is essential in raw materials. He instanced selenium, where electric and electronic equipment may have a higher claim than brighter milk-bottles Nor is there a reservoir of technical talent or of labour Technologists must be used sparingly The partially or fully automatic factory may go far in meeting labour shortage

Sir Ewart Smith, vice-chairman (now chairman) of the British Productivity Council, showed that, in spite of recent favourable trends, the rate of increase in productivity in Britain has been, for a considerable period, consistently less than in the United States, although at one time the rates had been the same We ought to aim at an increase of 10 per cent per annum in the hope that few would fall below 5 per cent and many would achieve 7 or 8 per cent with a reasonable number attaining 10 per cent He analysed the functions of research, management and operational study He indicated that the research outlook is essentially that which would provide the information and principles on which management decisions should be based and by which improved practice could be instituted on the shop floor The advantages of automatic operation must be balanced against maintenance work and first cost, but there is the opportunity of transferring labour from routine to interesting work Although research associations and such bodies cannot do industry's job, yet they can and must provide the basic information, the principles and the encouragement to hasten the industrial revolution which, as Sir Ben had said, is now on the way

In opening the discussion, Dr S Whitehead, chairman of the Committee of Directors of Research Associations, said that, additional to those research associations which have operational departments, many others decentralize such work He instanced certain difficulties, such as in making an economic case for change and capital investment, workers' co-operation in research, natural inertia and over-indulgence in pride in past achievement and standardization Nevertheless, research associations must sincerely accept the tasks put by Sir Ben and Sir Ewart both by making the necessary studies and in producing a favourable industrial climate of opinion Dr B K Blount, deputy secretary of the Department of Scientific and Industrial Research, remarked that the stations of the Department serve many industries and deal with problems of national well-being He gave instances to show their insistence on practical application to essential needs In addition, the Department has central services for studying efficiency and the human element, and to help in all kinds of operational research and information problems The general discussion turned on the best strategy of approach to industry, and specific problems such as local redundancy

In a session on materials, Mr. D A Oliver, director of the B S A Group Research Centre, said he thought that private enterprise could not unaided exploit mineral resources fully on a long-term plan owing to shortage of risk capital and man-power, insufficient technical resources, lack of information and the uncertainty of world conditions He proposed that the government should co-operate by the setting up of a minerals advisory bureau, the continuous study of consumer demand and the provision of a national mineral-dressing and process metallurgy laboratory Although the type of assistance proposed was agreed in the discussion, there were differences as to the mechanism and the institutions which should be responsible Prof S. Zuckerman stressed the desirability of living on income rather than capital Synthetics do not usually replace natural materials, he said they satisfy new needs and often make large demands upon non-renewable resources such as coal and oil Conversely, synthesis can shift the burden to renewable resources such as cellulose If photosynthesis could be understood and made efficient, solar energy and renewable organisms would be much better than chemical factories These considerations often conflict with short-term profitability, but we must strive towards the best balance, in which both productivity per acre and per man are important In the discussion the effort was mentioned that has already been made to reduce waste and recover used materials, though the present economic value of recovery does not always represent its ultimate value Pest destruction could give an immediate saving, and advance in fertilization would increase yield per acre, but in Prof Zuckerman's view there is a long way to go

Mr K. T Spencer, chief scientific adviser, Ministry of Fuel and Power, recalled that the industrial progress of Britain has been based on cheap coal. An expanded and competitive industrialization demands more fuel At best, nuclear energy will leave for ten years or more an increasing gap between demand and supply No spectacular increase in coal production has followed mechanization, and the quality has deteriorated We have provided for increased use of oil, but greater dependence on imports is ultimately unsatisfactory We must, therefore, use fuel more efficiently Railway electrification could save 13 million tons of large coal at the cost of 5 million tons of poor coal The domestic open fire is condemned anyhow by pollution Improvements in fuel efficiency have been achieved in collieries, in the ceramics, the iron and steel and the laundry industries, but comparisons show that there is great room for improvement in industry as a whole by the intelligent use of existing data Research associations could give a lead to industry in this and several have done so, but industry must respond to advice on this central essential problem irrespective of local incentives, since some industries are large coal users but have a low proportionate fuel cost

Dr W A MacFarlane, director of the National Industrial Fuel Efficiency Service, described the National Fuel Efficiency Service, which has taken over and expanded the service of the Ministry of Fuel and Power The Service finds sources of waste, improves operation, makes detailed inspections and full heat and power surveys He stressed the importance of data on low-pressure steam Mr O F Thompson's paper dealt with economic factors in the provision of low-cost energy in the future Research was urged on economic forecasting, capital resources and availability, and the effect of taxation In the discussion, attention was directed to what has been done in collieries, the advantages of pithead electrification, and the reduction between 1920 and 1938 from 1,550 tons to 670 tons needed to generate a million kWh, since 1938 the firing coal used for ceramics has fallen from nearly 1 25 to 0 4 million tons Economy is possible in the labour used in obtaining and using fuel Although water-power, wind-power, terrestrial heat and solar radiation might make no great contribution, they should be used There is no doubt as to the informed interest in fuel efficiency.

Prof C F Carter, of The Queen's University, Belfast, urged examination of the business hurdles which innovations must surmount—capital investment and risk, the amount and period of profitability, the uncertainties of markets and supplies, the interval required to achieve success He believes that nowadays managements are less willing to take risks, but, conversely, with full employment and an inflationary tendency, the risks are less. Dr R M Lodge, research manager of British Nylon Spinners, Ltd, in a paper on the economic factors in the planning of research, referred to economy in the use of scientists, the modern growth of team-work, freedom of atmosphere and the minimum and maximum of expenditure, which are related to the amount of development work This is much more costly than research and should be more carefully planned, bearing in mind production and sales Mr A H Wilson, director of research and development, Courtaulds, Ltd, in a paper on the economics of re-equipment, dealt with some of the questions raised by Prof Carter and discussed the economic effect of discarded plant when changing an existing industry as compared with founding a new industry Dr F M Lea, director of the Building Research Station, Department of Scientific and Industrial Research, illustrated in the building industry, where there are few large firms and not much capital, the influence of new machines (such as the tower crane) and methods on productivity and the organization to secure it He showed how these considerations have determined the work of the Building Research Station Mr R T Eddison, of the British Iron and Steel Research Association, used the example of the handling and transport of iron ore to show how the best compromise can be reached in choosing a method of working, when several different resources are needed which are differently, perhaps oppositely, affected by changes and where the simple criterion of cost might need some qualification The various discussions on these papers agreed as to the necessity of economic appraisal, but there was divergence as to how it should be done Similarly, the planning of research against the background of application was admitted, but not the detailed methods the mention of sponsored research provoked discordance The opinion was expressed that large concerns in the United States are no more venturesome than British industry It is clear that the study of the effect of innovation upon production and operation is widespread

The next two sessions were devoted to the human factor Mr R M Currie, head of the Central Work Study Department, Imperial Chemical Industries, Ltd, stressed the need for research into work study, which he said is an important tool in management and also is based on the same principles as scientific research, but its application must be direct and speedy Mr N Pleming, chairman and managing director of Associated Industrial Consultants, Ltd, added the further management tools of cost-control and production-planning and control He thought great improvements could be secured by existing methods, provided co-operation between management and workers is achieved Dr C B Frisby, director of the National Institute of Industrial Psychology, dealt with the adaptation of equipment and work organization to the anatomical and physiological characteristics of the worker This leads to psychophysical features which affect the skill of the worker Lastly, there are psychological aspects which influence the worker's attitude to his task and the satisfaction he gains, and here the relations between workers must be considered.

The two papers from trade union representatives showed some difference of attitude Mr L T Wright, general secretary, Amalgamated Weavers Association, believes that productivity is primarily the function of management, which must also convince the workers that they will benefit as human beings from changes general full employment is not an answer to particular local redundancy Although Mr Crawford, chairman of the National Union of Boot and Shoe Operatives, was as emphatic on a proper appeal to workers', natural human qualities, he considered that they can aid management both in planning and in encouraging a favourable response. He examined incentive schemes, rate-fixing and work-organization and gave examples of successful schemes which have been carefully planned and judiciously introduced to the workers The discussion indicated the general interest in work study, and that the same principles are applicable in many other branches of human activity Mr Crawford's opinion that workers would respond to well-conceived and well-expressed ideas seemed to be accepted

The summing-up of the conference was by Dr. A King (D S I R), Dr F C Toy (Shirley Institute), Mr F. Courtney Harwood (Launderers' Research Association), Mr S. H. Clarke (Fire Research, D.S.I.R.), the Hon. L. O. Russell (Institute of Management) and Sir Thomas Hutton (Productivity Council). The conference had shown how many resources are available for improving productivity and meeting its technical, its economic and its human problems. All these resources are not everywhere known or used. To overcome this there are two main national agencies. The British Productivity Council, with its decentralized regional organization and circuit system, endeavours to bring management and workers together in every main industrial area, making use of modern methods of presentation. The second agency is provided by the research associations and the Department of Scientific and Industrial Research with its stations. These bodies have valuable contacts with industry since they impinge directly on the particular industrial sectors of which they have expert knowledge. They have already done a great deal and are converted to the objects of the conference. Nevertheless, their structure, especially that of the research associations, permits them to do more; the value of the conference will depend upon whether it succeeded in establishing that interest in scientific and technological research should not limit the effort to convert industry as a whole to the principles which those attending the conference accepted.

X-RAY APPARATUS AND ASSOCIATED TECHNIQUES

EXHIBITION IN LONDON

As in previous years, an exhibition of X-ray apparatus was arranged in conjunction with the annual congress of the British Institute of Radiology, and was held at the Royal Horticultural Hall, London, during November 23–26. The majority of the exhibits were concerned with medical applications, both diagnostic and therapeutic, but industrial and scientific instruments were also represented.

Perhaps the most striking feature of modern electronic components and instruments is the way in which improvements in design and in materials have made possible reductions in size and in power consumption. This was well exemplified by much of the X-ray equipment on show. The increased use of oil-immersed components has resulted in compact single-unit power supplies for X-ray tubes, some of them incorporating series triode control valves which permit instantaneous high-tension switching as well as current and voltage stabilization. Another advance in this direction was represented by new oil-immersed high-tension rectifiers the filaments of which consist of thoriated tungsten with a power consumption less than one-third of that of pure tungsten filaments. Another interesting power supply includes a fly-wheel energy-storage generator which makes it possible to obtain a short-duration X-ray burst of very high intensity without drawing a heavy load from the mains supply.

X-ray tubes themselves have become more mobile; oil-insulated industrial tubes permit underwater radiography, and medical diagnostic and therapeutic tubes are mounted on cradles or above tilting tables which allow them and the patients to be moved automatically or with finger-tip control. Higher intensities are provided by the large range of rotating anode tubes. Another approach to the intensity problem in radiography is provided by the development of more-sensitive detecting devices. A new X-ray film is claimed to be 50 per cent faster than any previous type. Of even greater interest, perhaps, are the new image amplifiers, several examples of which were on show. In these tubes X-ray energy is first converted into light energy by a thin fluorescent screen, in contact with which is a photoelectric surface which, in turn, converts the light into electron emission. The electrons are accelerated by a high potential and focused on a final output screen. By these means the limit of brightness for threshold vision is reduced by a factor of 10 1, while the exposure time in fluorophotography is in the ratio of 200 1 as compared with the image produced on a normal fluoroscopic screen.

Artificial radioisotopes are becoming of ever-increasing importance both in therapy and in radiography. This fact was reflected in the many instruments on show for the handling and the detection and measurement of high-activity sources. The measuring instruments exhibited ranged from a simple 'nurse-proof' radiation monitor to fully automatic equipment capable of measuring the activities of up to 425 planchet-mounted samples to any desired degree of accuracy without any intervention from a human operator, the results being printed by the machine.

In X-ray therapy the deleterious effects of radiation on healthy tissue are now guarded against, so far as possible, by arrangements of ingenious geometry such as those employed in arc irradiation and in moving-beam methods. A new possible way of reducing radiation burns, which may be of great potential importance, is the discovery of the inhibitory effect of cortisone injections on acute X-ray damage to animal tissue. Discoveries like the last, together with apparatus as yet in the experimental stage, were demonstrated in a small scientific section at the exhibition. In general, the main commercial part of the exhibition demonstrated that the X-ray industry is quick in developing new ideas to a production stage.

U. W. Arndt

THE AGE OF THE UNIVERSE

The Philosophy of Science Group of the British Society for the History of Science last year offered a prize for "the best essay on 'What is the logical and scientific status of the concept of the temporal origin and age of the universe ?'" Twenty-six essays were submitted, and a selection of six of these is published as the major portion of the November issue of the *British Journal for the Philosophy of Science*. The subject is considered from various points of view, the competitors having been asked to "clarify the logical, theoretical and observational aspects of the idea of assigning a quantitative age to the Universe". Naturally the essays vary in the distribution of emphasis between these aspects, and in those published the evidence most relied on ranges from the almost entirely logical to the equally one-sided observational kind. The value of the publication as a whole is thus greatly enhanced, and one receives the impression that the editors have made a wise choice of contributions for the enlightenment of those who wish to obtain as comprehensive a view as possible of the whole problem

The particular solutions arrived at, which are quite properly advanced with caution, differ considerably, but these are of less significance than the arguments that lead up to them The essays should therefore be read in full if the greatest benefit is to be derived, but an indication of the conclusions may be of some interest M Scriven (Minnesota), from epistemological reasoning, concludes that "no verifiable claim can be made either that the Universe has a finite age or that it has not We may still believe that there is a difference between these claims but the difference is one that is not within the power of science to determine, nor will it ever be" J T Davies (London) provisionally accepts the age (about 4 × 10^9 years) given by linear extrapolation from the nebular recession hypothesis as being "the simplest interpretation of the observations and as being in excellent numerical accord with the age from independent investigations" of particular constituents of the universe E J Opik (Armagh) accepts the agreement (in general order of magnitude) of the ages given by various phenomena as suggesting an age not exceeding 6 × 10^9 years for the universe "in its present form and content" G J Whitrow (London) also lays stress on this agreement, which "strongly suggests that the universe has a finite age of some 4,000 million years" R Schlegel (Michigan) prefers the view that the universe is "atemporal"—that is, the concept of time is inapplicable to it as a whole He distinguishes this from the view that the age of the universe is infinite, for this would be a particular solution for a universe to which the time concept is applicable B Abramenko (Mannheim), though admitting that conclusions must be based on observational evidence which at present is inadequate to settle the matter finally, favours the view that time, like space, is curved, so that physical processes occur in cycles There is then no such thing as the age of the universe as a whole, and the indications of age from the various phenomena relate to the length of one cycle in the infinite succession of cycles Unlike most of the writers, however, he attaches more significance to the differences between these indications than to their agreement

All the more prominent systems of cosmology—general relativity, kinematical relativity, the 'steady state' theory involving continuous creation—are given some attention, but it is noteworthy that none of the essayists writes specifically from the point of view of any of them, indeed, the objective character of the approach throughout is a praiseworthy feature of the collection One point, however, would repay further elucidation More than one writer is evidently under the impression that, in the 'steady state' theory, nebulæ are assumed continually to pass out of the region of possible observation, at a finite distance from the observer, through attaining and surpassing the velocity of light Recent correspondence in *The Observatory* (74, 172, August 1954), however, suggests that this may be a misreading, notwithstanding that it is the apparent purport of the papers in which the theory was originally presented, and that in fact the theory assumes that the region observable in principle is infinite in extent, no nebula ever disappearing from it It is very desirable that some clear statement on this point should be made by the authors of the theory, to prevent further misunderstanding

ROYAL OBSERVATORY, CAPE OF GOOD HOPE

REPORT FOR 1953

THE report for 1953 of the Royal Observatory, Cape of Good Hope*, shows that an extensive programme of painting and repairs to the Observatory has been carried out, and dilapidations which accumulated during the war period have been practically overcome Redecorations, externally and internally, have been effected in a number of buildings and at the time of writing the report only the new office buildings, a residence and a few other minor items required attention In addition, electrical work has been carried out in some of the residences, a few extra trees have been planted, and it is hoped that a new hedge planted near the entrance gates will eventually provide some protection from the prevailing south-east wind

The reversible transit circle has been in regular use and has required little special maintenance, observations were made with it on 155 days, 187 evenings and 113 mornings The fitting of modern roller and thrust bearings to the declination axis of the Victoria telescope was completed in January, and the new cell made by Messrs Cox, Hargreaves and Thomson for the 24-in lens was then installed, this cell has resulted in a marked improvement in the performance of the lens A number of alterations have been made in other ways, among which may be mentioned the replacement of the old windscreen by a new all-canvas screen which allows observations to be made within a few degrees of the horizon instead of 30° as with the previous arrangement The telescope was used on fifty-seven nights for photoelectric observations, sixty-one nights for direct photography, and the astrometric camera that is mounted on it on forty-two nights The astrographic telescope, which was in continuous service, was used on one hundred and sixty-five nights for photoelectric photometry, on five nights for direct photography and on forty-eight nights for photography with the photometric cameras mounted on it This telescope, while still behaving fairly well in spite of its age, requires a thorough overhaul in its drive and clamping mechanism, and, in addition, the axles and bearings of the wheels carrying the dome are badly worn and will shortly need renewing

The 7-in telescope and the tower telescope have been used for observing occultations, and the former has also been used for visitors The tower telescope is not in good condition as the old stand is unsteady, and the lens requires repolishing The 6-in telescope has been in regular use for observing long-period variable stars, and has also been used for visitors and for observing occultations The photoheliograph has been used to take two photographs daily of the sun The camera is in fair condition, but the stand is old, the polar axis unsteady and the clock drive unreliable A few minor adjustments and alterations were necessary on the photometric cameras mounted on the astrographic telescope in November 1952, and the timing device was completed and brought into use The astrometric (or wide-angle lens) camera which was dismounted from the astrographic telescope in 1952 was mounted on the Victorian telescope when the work on the declination axis had been completed, and was used on forty-two nights during 1953.

---

* Report of Her Majesty's Astronomer at the Cape of Good Hope to the Secretary of the Admiralty for the Year 1953 Pp 11 (Cape of Good Hope Royal Observatory 1954)

Many other matters are dealt with under the following headings observations and reductions, stellar photometry, Radcliffe section, meteorological observations, publication of results, personnel establishment, and miscellaneous Under the first of these is included an account of the parallax programme, and, although the observations for the main part of the parallax programme were completed in 1951, a few extra plates were needed to complete the determination of the proper motions in declination. Since the start of the programme in 1926, the parallaxes of 1,792 stars have been determined, while 3,508 plates are waiting to be measured for parallax and a few hundred for proper motion. Parallaxes were derived for thirty-two stars, none of which had a parallax previously derived at the Cape. Under the heading of stellar photometry is included work on bright stars, and reference is made in this to the new bright star programme which includes all stars in the Yale Bright Star Catalogue between dec −4° and −64°, together with a number of fainter stars from the radial velocity and parallax lists. Observations are being made in two colours with the photoelectric photometer attached to the astrographic refractor The stars used in the previous programme, that is, those brighter than *HR* 5 0, are used as standards, observations being made, as previously, at 30° zenith distance Under the heading of miscellaneous, Dr. R H Stoy, H M Astronomer at the Cape, refers to his two short trips overseas, the first to attend the conference on the co-ordination of galactic research, which was held at Groningen, and the second to attend two conferences in the United States, one being on photoelectric photometry, and the other on astrometry. "These three conferences," remarks Dr. Stoy, "relating as they did directly to the work of this Observatory, proved to be very helpful in suggesting the most useful programmes for future work."

THE FUNCTION OF HYDROXYPROLINE IN COLLAGENS

By Dr. K. H. GUSTAVSON

Swedish Tanning Research Institute, Stockholm

Introduction

THE degree of intermolecular and interfibrillar stability of collagen to hydrothermal influence, that is, its resistance to heat in the fully hydrated state, is most conveniently measured by the temperature at which instantaneous shrinkage of the collagen fibres takes place (thermal shrinkage) In earlier investigations, it was found that the shrinkage temperature, T_s, of collagen from fish skin (Teleostei) is much lower than that of mammalian collagen, specimens of cod fish and of bovine skin mainly being investigated. Thus, native collagen of cod fish skin shrinks at temperatures of about 40° C. [1,2], when freely suspended, whereas bovine skin requires temperatures of about 65° C. For collagen of the skin of eel and freshwater fishes from Swedish lakes, T_s w found to be in the range 55–57° C. [2]. Regardin the hydrothermal stability of the corium, th fishes form two distinct groups (1) the col and deep-water fishes for which T_s of their sk is in the range 37–45° C , and (2) the warm- an surface-water fishes with values of 50–57° C During the past fifteen years, the shrinkage tem peratures of a large number of skins from variou species of salt- and fresh-water fishes in Swedis waters have been determined[1–7] Independentl Takahashi and Tanaka[8] have determined the shrinl age temperature of skin collagen from a great numb of fishes in Japanese waters, and they also find th values to fall into two distinct temperature-ranges

Earlier Findings

It was suggested in the early work on cod fis collagen[1,2,4], at a time when data for the amino-ac composition of mammalian collagen were far fro being quantitative and no reliable analysis of th amino-acid make-up of fish collagens was availabl that the marked difference in hydrothermal stabilit of bovine skin and cod-fish skin was probably n due to different chemical composition (amino-acid but rather was a problem of different intermolecula stabilization of the two main classes of collage Thus, in the final analysis, it should be a question molecular architecture and organization.

The following differences in chemical behaviour the collagens of skins of mammals and teleost (*Gadus*) have been found earlier[1–7,9–12] Collagen fish skin is more easily gelatinized than that mammalian skin. The former is also more extensivel degraded and solubilized by acids and alkalis and b trypsin than native bovine skin[1,2], which is prac tically unattacked by trypsin[13,14]. Thermal de naturation of fish collagen does not increase it reactivity towards large molecules, mainly inte acting with proteins by means of co-ordinate valenc forces (hydrogen bonding), for example, vegetab tannins, while the fixation of these agents by collage of bovine origin is drastically increased by denatur tion of the protein[4–7]. The reactivity of agen principally reacting with proteins by means electrovalency is practically identical for both typ of collagen, native as well as denaturated[4–7]

Irreversibly fixed polyacids show distinctly d ferent effects on the two types of collagen T bovine type is not markedly changed, and is in som respects stabilized by these agents, whereas c skin is practically destroyed by irreversible upta of the polyacids, T_s is much decreased and the fib strength is completely lost[9]. Additional characte ization has been obtained from investigations of t effect of anionic detergents such as sodium dodec sulphate in 5 per cent aqueous solution Cod sk was largely solubilized, whereas no permane alteration of bovine skin was found in these trea ments The unifunctional, non-swelling naphthalen β-sulphonic acid and polymetaphosphoric acids sho the same differences in their action on the two for of collagen[10]

In view of these observations and the fact that t acid- and alkali-binding capacities of the two typ of collagen were identical, it was suggested that t difference between the bovine and teleost (cod fis collagens should be principally one of molecul organization, the low degree of stability of t fish-skin collagen being ascribed to a less develop

Languages

IN research, technical know-how and publicity, these meticulously edited and ingeniously arranged dictionaries offer a new and precise basis for translation This first correlates English (and American), French, Spanish, Italian, Dutch and German, and as the subject is developing, it includes brief definitions Slang and jargon are not excluded The clear layout is that indicated by UNESCO research The author is W E CLASON, Head of the Translation Dept at Philips, Eindhoven 6¾ × 9 in, 600 pp *March*, £6

★ **Rubber** (10 languages); **Automobiles** (8), **Cinema, Sound, Music** (6), **Criminal Science** (8) are among many others being prepared

CHEMISTRY—NEW AND RECENT

Liquid-Liquid Extraction—Alders

A guide to extraction calculations, and their theory, to the measurements required, and to small-scale operations designed to forecast results, whether for research or in industry From the Shell labs, Amsterdam *Feb*, 32*s*

Solvents Manual & Chart—Marsden

First reviews tend to confirm this as the most lucid, easily-used reference on significant solvents ever compiled 70*s* The ingenious *Solubility Chart* also in a wall version, 12*s*

Theoretical Organic Chemistry

An Introduction—Hermans

The essential theory including many very recent advances, set out clearly for students with a minimum of mathematics *Just ready.* 38*s* 6*d*

Theoretical Principles of Organic Chemistry—Huckel

The long-awaited English version of **PROF HUCKEL'S** great work is a sound and stimulating guide to a vast field, from the modern viewpoint which he himself has done so much to establish Vol I (of 2), *March*, 77*s* 6*d*

Experimental Inorganic Chemistry

DODD-ROBINSON with its modern methods, interesting preparations and 1,500 references has been welcomed everywhere, especially for research labs 42*s*

Chemical Constitution—Ketelaar

This *Introduction to the Theory of the Chemical Bond*, by the Professor of Physical Chemistry at Amsterdam, is strikingly up to date, and stimulating to teacher, student or practising chemist 40*s*

MACMILLAN BOOKS

Intermediate Chemistry

Sixth Edition

T M LOWRY, C B E, M A, D Sc., F R S

Late Professor of Chemistry in the University of Cambridge

A C CAVELL, M.A, B Sc.,

Senior Science Master at Uppingham School

The main intention of this new edition of *Intermediate Chemistry* has been the re-writing of the Organic Section Several changes have been made to the Inorganic Section, and there have also been a number of other alterations to and extensions of the work, which is designed to provide a complete text-book of chemistry for Intermediate and General Certificate (Advanced and Scholarship) Examinations 18*s*

From Small Beginnings

E N. da C ANDRADE, D Sc, Ph D, LL D, F R.S

This little book is based on a series of six television talks given by Professor Andrade, and is the result of letters which were occasioned by them In it he deals with some of the experiments and thoughts behind a few simple scientific discoveries which have led to such advanced developments as the radio, the aeroplane, the motor car, and the electric lamp 3*s*. 6*d*

Semimicro Qualitative Analysis

A Course in Applied Chemical Equilibrium

EDWIN O. WIIG, Ph D, WILLARD R LINE, Ph D, and JOHN F FLAGG, Ph D

This revision of *Semimicro Qualitative Analysis*, while retaining the experimental procedures and much of the form of the earlier text, has been almost completely rewritten The theoretical section has been considerably expanded and a large number of problems of varying difficulty (with the answers to many of them) have been added The sections on special procedures for ferro- and high-aluminium alloys have been modified on the basis of student experience 25*s*

Guide for Safety in the Chemical Laboratory

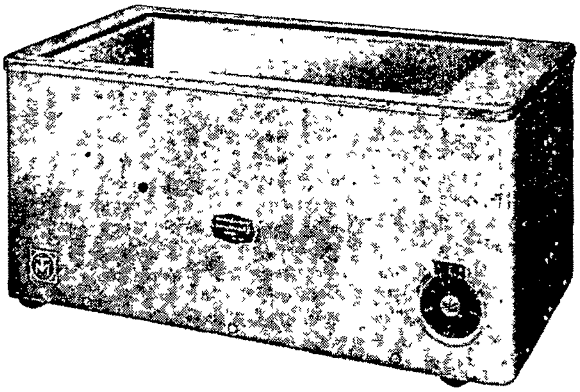
This book sets forth in detail recommended safety procedures for the storing, handling and use of chemicals in every form It is up to date in every way and covers, among other things, radioactive materials It should be kept as a guide and ready reference wherever chemicals are used 32*s*

All prices are net

St. Martin's Street, London, W.C.2

THE INCUBATING BATH

No S 771 or S 772



For really precision incubation of bacteria, etc , the normal oven is not sufficiently accurate

Many research laboratories now keep their test tube cultures in water baths when all errors due to unevenness of temperature are eliminated The speed with which the sample comes to temperature is also much greater

For this work we particularly recommend our simple baths as illustrated. They are normally in two depths and the clear internal sizes are —

23 in × 12 in × 6 in internal depth
23 in × 12 in × 10½ in internal depth
Accuracy ± 0 25°C

A NEW-PRINCIPLE A-C AUTOMATIC VOLTAGE STABILISER

We have now had released to us by a Government Department th design of our "A.C. Mains Regulator, Automatic, Step, Mark II", an are therefore manufacturing this unit for general sale. It ideally fills th need for a cheap, small and light Stabiliser. Although it measures onl 8¼in. x 4½in. x 5in., weighs as little as 11 lbs., and costs only £24 ne it has a performance fully equal to any similarly rated Automati Stabiliser of the resonated, saturated core type, without any of th disadvantages.

ASR-1150 has a pure output waveform, is unaffected by changes i mains frequency, and works equally well from no-load to full loa which is 1150 VA. It has a stabilised output at 230V unless otherwis ordered.

Many other Automatic Voltage Stabilisers are now manufactured b us, and all are available for immediate delivery. In some cases th constancy of output is as high as 0.15%. Models are available fror 200 VA to 30 kVA, single phase. 3-Phase Stabilisers are also availabl Prices are *extremely* competitive.

We can supply from stock all types of American tubes, condensers, valves, potentiometers, etc.

★*MEMO: If you are interested in infinitely-variable Transformers, do not forget the almost indispensable "VARIAC" (Reg'd. Trademark). Models are available from 170 VA to 21kVA. Our Catalogue V-549 (3rd Edition) tells the whole story, and will gladly be mailed free and post free, on request.*

The *NEW "ASR-1150"* costs only *£24* net

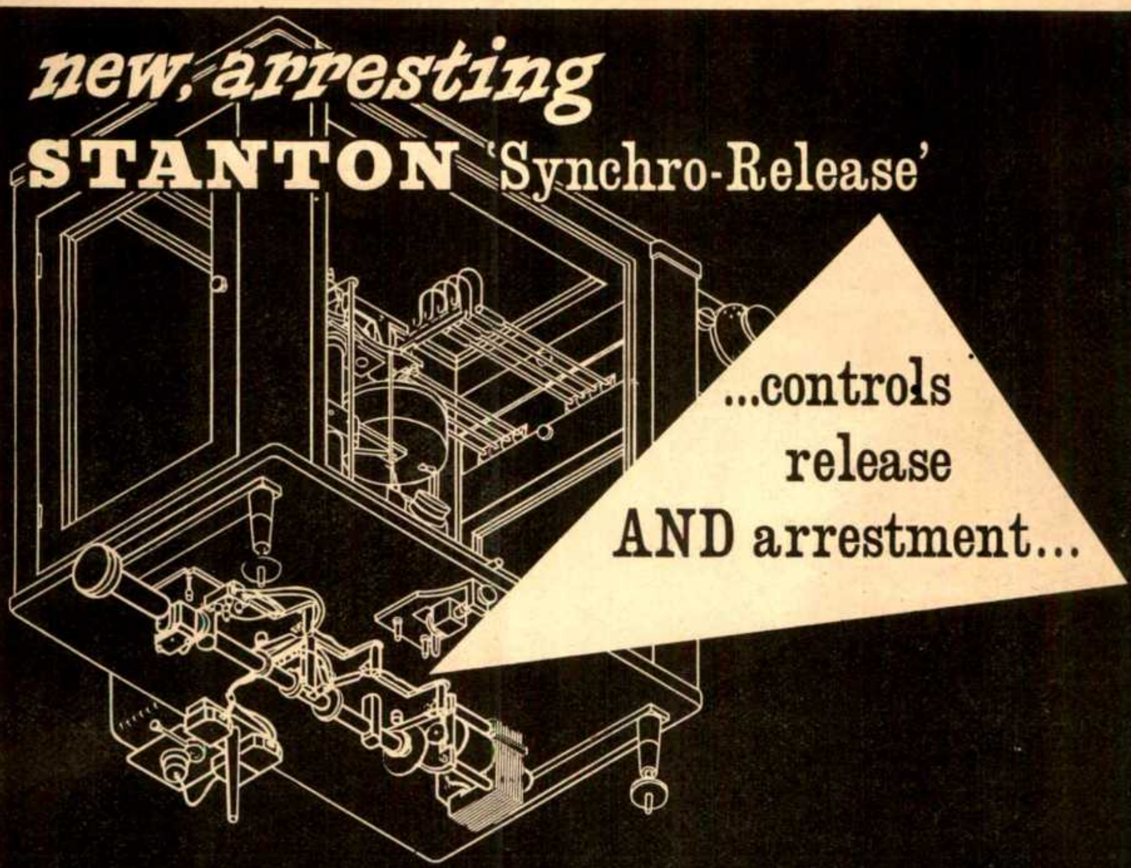
new, arresting

STANTON 'Synchro-Release'



brings knives and bearings smoothly into contact without impact -independently of the user

The most careful chemist could not release a balance more smoothly than the Stanton "Synchro-Release" device. So gently controlled is the automatic motion of the "Synchro-Release" mechanism that knife edges and bearings are brought into contact swiftly, safely, accurately, without the slightest jarring or vibration of impact no matter how hurried or unskilled the operator may be.

ALL Stanton balances can now be supplied with "Synchro-Release" giving these extra advantages:—

- **Safely controls arrestment as well as release.**
- **No loss in weighing time.**
- **Ensures sustained accuracy on routine weighings.**
- **Simple, sturdy synchronous device—nothing to go wrong.**
- **Facilitates training of laboratory personnel.**
- **Reduces balance operating costs.**

SEND TO-DAY *for illustrated leaflet giving full details of this amazing new improvement.*

For scientific electronics...

In its most advanced form, specialised production in electronics today calls for the combined skill, knowledge and experience of a diversity of scientists and technicians and may employ a similar diversity of resources at the stage of physical interpretation, if the sum of this intelligence is to result in the most efficient end product.

Plessey number all these facilities, and many others, as closely integrated parts of a single division — the Electronics Division — and are, in consequence, able to offer a rare if not unique service to manufacturers for the limited or quantity production of their products.

Among those renowned organisations which have current contracts with Plessey are included BTH, Decca, IAL, Kelvin Hughes, Marconi's Wireless Telegraph Company Ltd., and Laurence Scott & Electromotors Ltd.

Stop Watches

OUR improved model 308 stop-watch is now available for delivery from stock. The watch is specially timed at the factory to conform with the requirements of the Ministry of Fuel and Power (Elec. Supply Meters Act, 1936) and the requirements of the N.P.L. for a high grade stop watch with a 1/30th second escapement suitable for laboratory use.

The dial is calibrated 0-10 mins., the large hand making 1 revolution in 10 secs. The size of the watch, 22 ligne, with a dial diameter of 1¾ in., allows the use of a very open scale thus facilitating the reading of the sub-divisions which are graduated 1/20 sec.

Black or white dials are available and we are prepared to luminise the hands and figures to special order.

A comprehensive range of stop-watches is available for all purposes.
A copy of our new illustrated catalogue will be gladly sent on request.

FOR pH CONTROL

JOHNSONS OF HENDON offer to chemists and manufacturers this useful series of five test papers for the measurement of pH values. UNIVERSAL is one paper covering completely the range from pH 1 to pH 10, enabling pH values to be checked to within 0.5 pH. COMPARATOR test papers make a set of four separate indicators for obtaining still greater accuracy by determining the pH value of any solution to within 0.3 pH.

Descriptive leaflet will be sent free on request.

"Finger-tip flame control"

said a silversmith, "Pleasant to handle, very sensitive controls."
He was one of the many users of our Flamemaster Mark II and the three comments he made probably sum up the main reasons for the Flamemaster's immense popularity.
Also:

It burns coal-gas or bottled-gases of the butane type with equal efficiency . . .
The air or oxygen pressure needed is comparatively low . . .
All the different flame-units are easily interchangeable . . .
It won't splutter or give you an unstable flame . . .
It won't leak, even on high pressures . . .
It won't raise your running-costs, (our economiser-trigger sees to that) . . .
But it *will* bring speedy and reliably controlled heating right to the spot where you need it . . .

remember the name

FLAMEMASTER MARK II

intermolecular cross-linking of the protein chains, compared to bovine collagen[1-2]. The titration curves also showed close similarity, only with a slight deviation of the curve in the pH range 3–9, pointing to more easily discharged ionic groups (salt links) in the case of fish collagen[10].

In view of these findings, the following working hypothesis of the structural organization was advanced. Mammalian-skin collagen, with its intertwining fibre bundles, is mainly stabilized by means of hydrogen-bond bridges between laterally located keto-imide groups. Salt links of electrostatic nature probably supplement these primary cohesive forces. In fish-skin collagen, with parallel grouped layers without any marked interlacing of fibre bundles, on the other hand, the low degree of stabilization of the structure may be accounted for by the assumption that the hydrogen bonding is only weakly developed, electrovalent cross-linking being responsible for a great deal of the structural cohesion.

This finding that the irreversible inactivation of the ionic groups of fish collagen by means of non-swelling agents, specific for these groups (eliminating the electrovalent cross-links), leads to a drastic lowering of the stability and mechanical strength of the fibres would then be due to the fact that these salt links are to a great extent responsible for the cross-linking, hydrogen bonding being less developed. On the other hand, the structural properties of mammalian collagen, mainly stabilized by cross-links of the hydrogen-bond type, are not materially impaired by the elimination of the salt links by discharge, since the ionic interchain forces contribute only slightly to the molecular cohesion, the dominant cross-links being of the hydrogen-bond type, which are not involved in the fixation of the agents specific for electrovalent protein groups.

This view is supported by some additional findings: (1) The general properties and the reactivity of fish-skin collagen resemble those of bovine collagen which has been pretreated with lyotropic agents, such as concentrated solutions of urea, the main effect of which is to rupture interchain links of the type of hydrogen bonds and make sites of reaction available in the protein[4]; (2) Nutting and Borasky[15] found the electron-microscopic picture of shark-skin collagen to be similar to that of bovine collagen which had been degraded by prolonged alkali treatment (liming).

Amino-acid Composition

Further progress became feasible with the advent of complete data on the amino-acid composition of mammalian collagen[16] and of the corresponding data for fish collagen[17]. The main difference between collagen of mammals and teleosts is the low content of hydroxyproline (9 per cent) of fish-skin collagen (halibut[18], shark[19]) compared to the figure of 14 per cent for bovine collagen, apart from minor divergences in amino-acids present in small amounts, such as serine, threonine and methionine[17]. Hence, the possibility of the hydroxy group of the hydroxyproline residue being involved in the intermolecular linking of collagen is obvious[3]. The original view of the less-developed intermolecular hydrogen bonding on the peptide links of fish collagen may then have to be modified, with due attention to the possible function of the hydroxy groups in the interchain linking[3].

In view of the different hydrothermal stability of skins of warm- and cold-water fishes, their contents of hydroxyproline and proline should be of interest, particularly for ascertaining whether there exists any relation between the contents of pyrrolidine residues and the T_s of the collagens. The possible function of the hydroxyproline residue for stabilizing collagen has been suggested by Borasky[19] and the present author[3,20]. In a preliminary note on the hydroxyproline contents of mammalian collagen and of the two types of teleost collagens, such an interdependence was reported[3]. This finding has been independently verified by Takahashi[21]. On investigating skins of some fifty-odd species of fishes, Takahashi[21] found 7–9 per cent hydroxyproline in skins of cold-water fishes, with T_s in the range 34–44° C. The great majority of species contained 8 per cent. The corresponding values of the skins of warm-water fishes, with T_s 50–58° C, were 10–12 per cent. The figures for bovine hide and gelatin were 12·5 and 13·4 per cent, respectively. The lowest value of hydroxyproline, 7·0 per cent, was found for the skin of the rock-fish (*Sebastodes baramenuke*), which also showed the lowest T_s ever recorded for collagens, namely, 33–34° C. The highest values of T_s and hydroxyproline were recorded for the skin of the carp (*Cyprinus carpio*) with 57° C and 11·6 per cent, respectively[21].

The available data on the content of hydroxyproline have been obtained by the method of Neuman and Logan[18]. The accuracy and reproducibility of this method is not as great as could be desired, and since indirect values only are obtained by this technique, a direct estimation of this imino-acid was imperative. By a combination of the Moore–Stein chromatographic procedures on columns of starch[22-25] and on 'Dowex-50'[25,26], according to the modification of Åqvist[27], the contents of hydroxyproline and proline of collagens of skins from mammals and from representative species of the two main groups of Teleostei have been estimated by Dr. S. Åqvist.

Materials and Methods

Isoelectric collagen of calf-skin pelt (lightly limed for unhairing) represented the mammalian collagen. Specimens of skins of cod fish (*Gadus morrhua*) and of pike (*Esox lucius*) were selected as typical cold-water and warm-water fishes. The fish skins were not subjected to any alkali treatment. After mechanical removal of scales, adipose tissue and other non-dermal matter, the fresh skins were soaked for 24 hr. in a 10 per cent solution of sodium chloride and saturated with toluene, at 5° C, in order to remove globular and other accessory proteins. The skins were washed and drummed in cold water until free from chloride ions. The acetone-dehydrated skins were then extracted with petroleum ether and finally acetone-dehydrated. The T_s values of the skins were determined by the conventional method on freely suspended strips of both fresh and purified skins. Identical T_s values were found. Six determinations were carried out on each skin. The samples were taken from different parts of the skin, cut in dorsal and ventral directions, from six specimens. The acid-binding capacity was determined indirectly by estimating the acid removed by 500 mgm. collagen in the form of small cubes, from 10·0 ml. of 0·1 M hydrochloric acid, one-molar in sodium chloride, upon 4 hr. shaking, titrating the residual solution to pH 5.

The estimation of proline and hydroxyproline was carried out on 500 mgm. samples of skin substance,

Table 1. GENERAL CHARACTERISTICS OF COLLAGENS

No.	Type of skin	T_s in °C	Per cent total nitrogen on ash- and fat-free dry substance	Per cent ash	Acid-binding capacity in m*M* hydrochloric acid/gm. collagen
1	Cod fish (*Gadus morrhua*)	40	18.3	0.8	0.92
2	Pike (*Esox lucius*)	55	18.4	1.0	0.93
3	Calf (*Bos taurus*)	65	18.3	0.05	0.90

which was refluxed with 6 *M* hydrochloric acid for 36 hr. The first separation was on a column (300 mm. × 80 mm.) of a special starch. The column was washed with 8 litres of propanol–hydrochloric acid (1:1) and finally equilibrated with a solution of propanol–0.5 *M* hydrochloric acid (2:1). Portions of 200 mgm. protein were applied. This solution was made 0.5 *M* in hydrochloric acid and the double volume of propanol added. Hourly fractions were collected with the aid of a time-controlled fraction collector. For localization of the position and for identification of the amino-acids, the photometric ninhydrin method of Moore and Stein[22,23] was applied to 0.05 ml. of each fraction. The fractions were also located on a paper chromatogram, which is particularly useful for examination of overlapping fractions of hydroxyproline. The proline came out in fractions essentially pure after collecting 4 litres of eluate, and the hydroxyproline fractions after running 6 litres. The volume of the collected fractions of each amino-acid was about 800 ml. The hydroxyproline fractions were contaminated with threonine, and contained also smaller amounts of alanine, glutamic and aspartic acids. Therefore, a re-separation was necessary for hydroxyproline, and also for the proline in order to remove non-protein nitrogen (ammonia), due to contamination during the various operations. The collected fractions were evaporated *in vacuo* and dissolved in *M* hydrochloric acid. The final separation was on a column of 'Dowex-50', using the 'colloidal' type of 250–500 mesh, operated on the hydrogen cycle. The column was 20 mm. × 800 mm. *M* hydrochloric acid was used as eluting solvent. The resolving power of this column was excellent. Pure fractions of proline and hydroxyproline were collected in a comparatively small volume. The contents of the prolines were estimated by the micro-Kjeldahl method, since no satisfactory colorimetric methods for the prolines are available.

Data on the general characterization of the three types of skin collagen are given in Table 1. The results of the imino-acid analysis are shown in Table 2.

Discussion

General aspects. The collagen group of proteins is characterized by the prominence of proline and hydroxyproline, and the paucity of aromatic residues. Particularly the large amount of hydroxyproline is unique, and also important for the characterization of collagen as a class and for its estimation (Neuman and Logan[18], van Robertson[28-30]). The great variation of the hydroxyproline content o collagen from various sources, from 6 to 14 per cent, necessitates consideration of the origin of the collagen. Reference may be made to Bear's lucid discussion[31] on the classification of the collagen family. Further, approximately every third amino-acid residue of collagen is generally considered to be a pyrrolidine residue. This proportion is an integra part of recent models of collagen (Astbury[32], Pauling and Corey[33] and Bear[31]). Besides this regula sequence, Pauling and Corey[34] suggest occasiona units of one residue of prolines of four residue (seven 1:3 and four 1:4). The present results show that in some teleost collagens the proportion is scarcely half the number assumed.

The markedly different degree of hydrotherma stability of the skins of the two types of fishes is probably related to the different habitat, and possibly is of biological significance.

The results from investigation of numerous species of fishes show that there is a definite connexion between the hydrothermal stability and the hydroxyproline content of collagen. With decreasing percentages of this residue, the T_s of collagen is lowered, the maximum difference being more than 30 deg. C. (68° and 34°). Obviously, this is no evidence in itself for the view that the hydroxyproline residue is directly involved in the stabilization of the collagen, for example, by forming a site for an interchain hydrogen bond. The effect of the irregularity of the polypeptide chains imposed by the incorporation of the prolines may be indirect, and even fortuitous.

If collagen is mainly stabilized by interchain hydrogen bonds on oppositely located keto-imide groups of adjacent chains, the content of pyrrolidine residues should be a factor of importance. The residues of the prolines which are built into the polypeptide chains with the formation of —CO·N= links introduce a regular interruption of the normal —CO·NH— links, formed by the remainder of the amino-acid residues. Accordingly, sites for the compensation of adjacent —CO-groups of the keto-imide links are withdrawn, which implies fewer stabilizing cross-links and consequently a lowered degree of stability[35]. Then, mammalian collagen should be less stable to heat than fish collagen. However, the reverse is true.

Interchain hydrogen bond between hydroxy and keto-imide groups. On the other hand, supposing that the hydroxy groups of the residues of the hydroxyamino-acids may enter into interchain hydrogen bonding with some other groups, for example, the carboxyl, or the carbonyl of the —CO·NH— linkage, the stability of the structure would be expected to increase with the content of hydroxyproline, as is actually found[3,21].

The effect of the hydroxyproline on the degree of stability and reactivity of collagen was first examined

Table 2. PROLINE AND HYDROXYPROLINE CONTENTS OF COLLAGENS

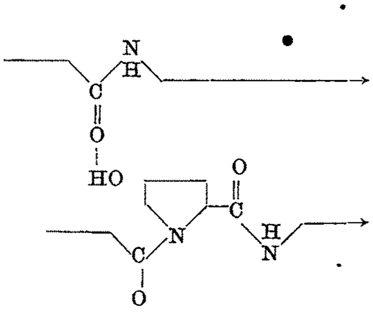
No.	Type of skin	Proline		Hydroxyproline		Proline + hydroxyproline	
		Per cent on protein	Per cent of total nitrogen	Per cent on protein	Per cent of total nitrogen	Per cent on protein	Per cent of total nitrogen
1	Cod fish	10.8	7.2	5.8	3.4	16.6	10.6
2	Pike	13.3	8.8	7.9	4.6	21.2	13.4
3	Bovine (calf)	14.1	9.5	12.7	7.4	26.8	16.9

the light of Klotz's concept[36-39], according to hich the hydroxy groups of the residues of the iphatic hydroxyamino-acids form strong hydrogen onds with the carboxyl ions in some globular roteins This linkage has been shown to affect the activity of the carboxyl ion[38] The reactions of ovine and cod-skin collagen with the simple cupric n, and with a number of complex chromium compounds, dyestuffs and non-electrolytes, have been udied in the isoelectric range of collagen The esults could not readily be reconciled with an xtension of the Klotz concept to collagens Morever, according to Bear[31], the electron-optical vidence suggests the presence of the residues of the rolines in the interbands, whereas the bands should ontain the residues of the dicarboxylic amino-acids ence, the formation of the —OH—O$\overline{\text{C}}$O— bond ppears improbable sterically

A satisfactory explanation of the correlation of the ydroxyproline content of collagens and their T_s, nd indications of the type of link formed, have been rived at by investigations of the behaviour of xhaustively acetylated bovine collagen Such a ollagen with all its amino-groups (0 39 m mol /gm ollagen) and 80 per cent of its hydroxy groups activated (1 39 m mol /gm collagen) was obtained y acetylating hide powder and calfskin, according the method of Green *et al* [40] Comparative experiments with N-acetylated collagen were included The ydrothermal stability of collagen is not affected by s N-acetylation, while the N- and O-acetylation, at is, the blocking of the hydroxy- and aminooups, lowers the T_s from 64–66° C to 40–44° C [12] his finding indicates the rupture of *interchain* oss-links by the O-acetylation.

Assuming that the aliphatic hydroxy groups are eferentially acetylated, at least 0 8 m mol. of ydroxyproline per gm collagen should have acted Hence, out of 1 07 m mol hydroxyproline sidues of the original collagen[16], three out of four ydroxy groups have been blocked. In this connexion, it is of interest to note that T_s for the acetylated bovine collagen coincides with that the skins of most cold-water fish, suggesting at the hydroxy group resisting acetylation forms stronger bond than the rest of the hydroxy oups, and further that this particular group is ainly responsible for the stabilization of the teleost llagen

From the investigations of the effect of the intivation of the hydroxy groups of collagen on its activity, the results from series with condensed getable tannins (mimosa) and non-ionic complexes sulphito–chromium sulphates are most instructive e fixation of these compounds by collagen is preciably increased by its heat-denaturation, and its pretreatment with lyotropic agents, indicating at the irreversible fixation of these compounds by llagen involves non-ionic protein groups (hydrogen nding)[4]. The mimosa tannins are mainly fixed by drogen bonding of the polyphenolic structures on e carbonyl oxygen of the keto-imide group[41,43] e very marked affinity of the condensed tannins for odified polyamides, which contain the —CO NH— kage as the principal site of binding, is the crucial oof[41] It is important to note that the non-ionic romium complexes are not bound by the polyaides[42,43]. Hence, they are probably not reacting th the keto-imide linkage of collagen Accordingly, e increased fixation of these chromium complexes heat-denaturation of collagen and by its pretreatment with lyotropic agents (urea, for example) cannot be due to the freeing of co-ordination sites on the —CO NH— linkages By O-acetylation of collagen, the irreversible binding of mimosa tannins by collagen is greatly increased, from 60 to 95–105 per cent, on the basis of protein On the other hand, the fixation of the non-ionic chromium complexes is markedly impaired by the blocking of the hydroxy groups by acetylation, decreases of the order of 30 per cent being commonly found These findings, with due regard for other facts which cannot be enumerated here, are in harmony with the view that a part of the hydroxy groups is linked by a hydrogen bond to the keto-imide group, schematically, as



The rupture of such a bond by heat denaturation, or by the lyotropic pretreatments mentioned, should satisfactorily explain both the increased fixation of vegetable tannins (by the freed —CO NH— bond) and of the non-ionic chromium complexes (by the freed OH— bond), as well as the effects of the blocking of the hydroxy group, that is, the impaired hydroxy-co-ordination of the chromium compounds, on one hand, and the increased binding of the keto-imide-attached polyphenols, on the other. The large decrease of T_s recorded ($\Delta T_s = -22$ deg. C.) is also explained. In view of the marked affinity of the native collagen for the agents mentioned, it is probable that only a few of the hydroxy and keto-imide groups are participating in this interchain cross-linking

The following considerations suggest that the hydroxy group involved is mainly furnished by the hydroxyproline residue. In the presence of an aliphatic OH group in intermolecular cross-linking, the teleost collagen should form a more stable structure than the bovine type, since the fish collagen contains more such hydroxy groups than the bovine collagen In view of the reverse trend of the shrinkage temperature, aliphatic hydroxy groups are not likely to be involved to any great extent

According to Prof R S Bear, of the Massachusetts Institute of Technology, the interchain cross-link suggested can be accommodated in the present helical model of collagen without difficulty[44]

The cross-link common to collagens generally The strong bond forming the mainstay of the collagen structure, which the masked hydroxy group is indicated to form, is probably an ester bond, the —O CO— link. The origin of the hydroxy group in this link is not known Experimental evidence for such a link in procollagen has recently been obtained by Grassmann *et al* [45] Further, the insolubility of collagen in saturated lithium bromide solution, which dissolves hydrogen-bonded structures, suggests the presence of some type of a strong bond in collagen (Alexander, personal communication) Moreover, the increase of the fixation of safranine O by collagen from 0 4 to 0 9 mgm equiv per gm collagen, found by Veis and Cohen[46] on denaturing collagen by heating it in water at 60° for 1 hr , supports this view, as does also the marked difference in alkali binding of limed collagen and gelatin, with due correction for amide groups, possibly due to the splitting of the ester bond in the alkali-processing of gelatin (Gustavson, unpublished results) As to the hydrogen bond suggested, it should be noted that, in Huggins's new collagen helix[47], the computed distance between the hydroxy group of the hydroxyproline residue and the carbonyl oxygen in the next turn of the helix is 2 9 A , indicating OHO hydrogen bonding (intrahelical)

For the direct estimation of the prolines, I am indebted to Dr S Åqvist, Karolinska Institutet, Stockholm. Research grants from Statens Tekniska Forskningsråd are gratefully acknowledged, as are also the personal communications noted in the references

ANTERIOR-PITUITARY - HYPOTHALAMIC RELATIONS IN THE FERRET

By A P. D THOMSON
and PROF S ZUCKERMAN, C B , F R S
Department of Anatomy, University of Birmingham

A WEALTH of observation has firmly establish
the fact that the anterior lobe of the pituita
gland plays a vital part in the control of growth a
reproduction, and also in several metabolic process
which cannot be classified under these two hea
On the other hand, views about the way its vario
activities are integrated and controlled remain ve
elementary They are broadly of two kinds T
first is that any specific activity of the anter
pituitary, at any given moment, is modulated by
feed-back mechanism in which the determining fac
is the level of secretion of the peripheral endocri
tissue which the pituitary gland may be stimulati
For example, as its titre in the blood rises, t
œstrogen that is secreted by ovarian tissue wh
stimulated by the anterior-pituitary follicle-stim
lating and luteinizing hormones checks the furth
secretion of FSH The second kind of explanation
that the hypothalamus directly controls certa
anterior pituitary functions An illustration of th
presumed control is the process of ovulation
animals such as the rabbit, which normally ovula
only after the stimulus of mating The immedia
cause of ovulation is the sudden release of luteinizi
hormone, and the belief is that the act of mating se
up a train of nervous stimulation which culminat
in the firing of certain hypothalamic neurons, a
that these, in turn, stimulate the anterior pituita
to discharge luteinizing hormone It has also be
suggested that the hypothalamus, by influencing t
discharge of luteinizing hormone, controls t
periodicity of the phases of the œstrous cycle
mammals in which ovulation is spontaneous
further example of this presumed hypothalan
control is the release of adrenocorticotrophic hormo
by the anterior pituitary under certain conditions
stress

Since there is reason for doubting whether t
axons of hypothalamic neurons actually innerva
the anterior pituitary gland, the view has be
advanced—and now has considerable currency—th
certain hypothalamic neurons discharge a chemi
substance which passes down their axons and diffu
into the primary capillary loops of the pituita
portal vessels, through which it passes into t
sinusoids of the anterior lobe This chemical su
stance is the presumed proximate stimulus for t
specific activation of the secretory cells in t
anterior lobe

This simple hypothesis is primarily based up
clinical and experimental observations which sh
that changes in, or stimulation of, certain regions
the hypothalamus may affect processes in which t
anterior pituitary is definitely concerned (for examp
ovulation in the rabbit). But the rest is suppositi
In the first place, there is no evidence that un
normal conditions the hypothalamus is a spec
relay station in the chain of stimulation of t
pituitary which begins, say, either with the act
mating or with a condition of stress Secondly,
the hypothalamus is a relay station, it is not kno

which nuclei are involved in the different responses of the pituitary, or by what specific nervous pathways they themselves are activated. Thirdly, no one has isolated or identified the presumed chemotransmitters which activate the anterior pituitary, and which the hypothalamic neurons are supposed to liberate; nor has any thought been given to the question whether the same degree of specificity applies to the assumed hypothalamic secretions as it supposedly does to those of the anterior pituitary. Fourthly, no proof has been given of the passage of chemotransmitters down the pituitary portal vessels. The only experimental 'proof' which has been offered in defence of the hypothesis is that certain processes in which the anterior pituitary is involved no longer occur when the pituitary gland is transplanted from its normal site, or after the pituitary stalk is effectively divided and the pituitary portal vessels have been prevented from regenerating.

The present communication is mainly concerned with the latter question, and with the part played by the pituitary portal vessels. Donovan and Harris[1] have recently described certain experiments from which they conclude that "the hypophysial portal vessels form a necessary part of the pathway of the light-induced œstrous response in the ferret". They base this view on the fact that one of six ferrets which were subjected to "simple stalk section", and eleven of fourteen in which the stalk was divided and a paper plate inserted between its proximal and distal stumps, failed to come into heat when exposed to artificial light during the winter months. In these animals there were "few, if any, vascular connexions between the median eminence and anterior pituitary gland". In those animals which responded to the light, vascular connexions were always present.

The essential argument here is that something failed to happen when certain vessels were few or absent. In its negative quality the evidence is thus similar to other observations which Harris[2] has adduced in support of his views about the function of the pituitary portal vessels. In the present instance, however, Donovan and Harris's experimental findings differ from some we have reported, and they are therefore concerned to find an explanation for the difference. The first point they make is a collateral one, and concerns certain of our findings which show that, while light acting on the retina accelerates œstrus in the normal, but not in the blind ferret, animals blinded in one season tend to come into heat in the years which follow at the same time as do normal controls[4]. Donovan and Harris hold that the experiments from which this conclusion derives are unconvincing, and their contention is that the animals concerned were not blind. They base this view on the fact that no 'anatomical proof' of blindness was given for sixteen animals in which the operative lesions were in the optic chiasma. But they have apparently overlooked the fact that, of the other forty-two animals in the experiment, eight had had their optic nerves, including sheath, and the remaining thirty-four their optic nerves, excluding sheath, divided. Whether the sixteen animals with lesions in the optic chiasma suffered only from form blindness, for which they were tested, there can be no question that the remaining forty-two were blind in the full connotation of the term.

The second point which they make about our work concerns the pituitary portal vessels. They state that our conclusion—that the vessels do not play an essential part in the response—is based only on the fact that two of our stalk-sectioned ferrets which reacted to the light stimulus were found to lack any vascular connexions between the floor of the hypothalamus and the anterior pituitary. This statement is only partly true. Our conclusion is derived from the fact that the response, whether positive or negative, is independent of the presence (or re-establishment) of a direct vascular link after stalk section. Presumably, however, in concentrating on the two particular ferrets to which they refer, Donovan and Harris appreciate what T. E. Huxley[3] put so well in 1863, that "every hypothesis is bound to explain, or, at any rate, not be inconsistent with, the whole of the facts which it professes to account for, . . . One fact with which it is positively inconsistent is worth as much, and as powerful in negativing the hypothesis, as five hundred".

Apart from the question of numbers, Donovan and Harris make three points about these two of our preparations. The first is that our operative approach to the pituitary stalk was not as good as theirs. Whether or not this is true, the point is quite immaterial. What matters is that we have obtained preparations in which the pituitary gland was completely sealed off from direct vascular connexion with the hypothalamus, and in which positive responses to light occurred. Their second point is that it is easier to get a clear picture of the vascular anatomy of the pituitary with sections 100 μ and 200 μ thick than with the thin sections of 10 μ which we have used. And their third, that when they examined the pituitary region of one of the two preparations to which they refer, they found that "a significant proportion of the visible blood vessels did not contain Indian ink". Had Prof. Harris and Mr. Donovan had more time for their examination, they would have seen that these two remarks are incorrect, if by them they mean to imply that 10-μ sections are inadequate to reveal the vascular anatomy of our preparations. Injected vessels are present in every section, and everywhere except where they should be according to the hypothesis that Donovan and Harris are defending. Furthermore, in the preparation in question, a barrier of cellulose (paper) surrounded by reaction tissue completely seals off the median eminence from the anterior lobe, and there is no direct nervous or vascular connexion of any kind between the pituitary on one hand and the base of the brain on the other. This is fully illustrated in the complete account of these experiments[5].

Since the point is of critical importance to the hypothesis which Donovan and Harris are defending, we have made a three-dimensional wax reconstruction of the serial sections of the pituitary region of yet another ferret (reported on for the first time here) which responded to light after the pituitary stalk had been divided and a plate of waxed paper inserted between its proximal and distal stumps. The animal lived for six months after the operation, and the paper became completely surrounded by reaction tissue. The sella turcica containing the pars distalis of the pituitary (the neural process having completely involuted) was roofed over by a massive barrier consisting of a double plate of new bone containing in its interior a mesh of cellulose (Fig. 1). The sections do not reveal any direct vascular connexion between the anterior pituitary and the floor of the brain, but show that the remains of the pituitary portal channels emptied into the vessels of the fibrous reaction tissue on the upper surface of the bone and cellulose barrier. The new bone surrounding

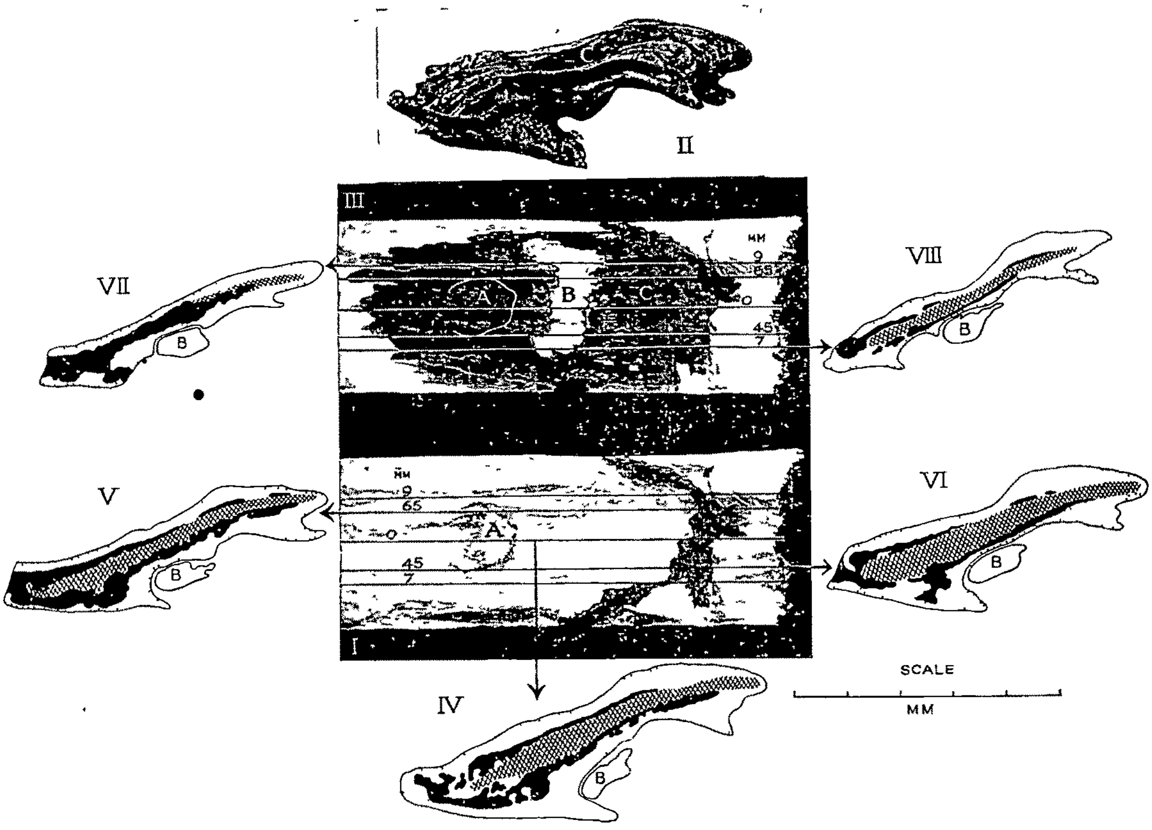

Fig 1 Wax reconstruction of serial sections of pituitary region in a ferret (*T F* 836)

I Floor of hypothalamus, showing median eminence and remains of proximal stump of pituitary stalk (*A*)
II Side view of block of reaction tissue (*C*) which separated the pituitary gland (*B*) from the floor of the hypothalamus It consists of a core of cellulose surrounded by new bone and fibrous tissue
III Block of reaction tissue (*C*) in position between base of brain and pituitary gland (*B*) The position of the median eminence and proximal stump of the pituitary stalk (*A*) has been projected on to the surface and is outlined in white
IV–VIII The five lines intersecting I and III mark the sagittal planes, through the block of reaction tissue, that are illustrated in IV–VIII The position of the anterior pituitary is indicated on each of these figures stippled area, fibrous tissue, solid black, new bone, cross-hatching, broken-up cellulose, *B*, anterior pituitary

the cellulose extended laterally well beyond the margins of the median eminence, and where bone faded out towards the lateral edges of the barrier, the seal separating the pituitary from the lateral part of the floor of the hypothalamus consisted of dense fibrous tissue over which the dura was intact Whether any chemotransmitters, if such exist, that may have passed from the floor of the hypothalamus into the reaction tissue finally reached the anterior pituitary through the systemic circulation does not concern the question under dispute—the proposition that the pituitary portal vessels are essential to the response of the anœstrous ferret to light

The purpose of our experiments has all along been to test Harris's hypothesis by transforming it into the positive question Is a vascular connexion with the median eminence either (*a*) sufficient, other things being equal, or (*b*) necessary for a positive response to light ? And the answer to both questions is no. The proof that a vascular connexion is not sufficient is that in cases where one is present, the response has failed to occur, and more decisive, the proof that it is not necessary is that the response occurs in the complete absence of any direct vascular connexion For these reasons we hold that Harris's hypothesis is untenable The fact that our now extensive investigations reveal many more instances of ferrets failing to respond to light after surgical interference in the region of the pituitary stalk than those now reported by Donovan and Harri does not affect the argument It does, howeve call for explanation We ourselves do not kno why animals that have been subjected to an operation in the region of the pituitary stalk so frequently manifest hypofunction of the pituitary, bu suspect, as do many workers other than Donova and Harris, that it may be due to pathologica changes in the pituitary following on damage to it blood supply, of which the portal vessels constitut a most important element Anyone who has experience of operating in so small an area as that whic surrounds the pituitary gland in an animal the siz of a ferret, and who appreciates how the actua disposition of blood vessels varies from specimen t specimen, will know how difficult it is either to limi or standardize this kind of damage Neverthele our experience shows that it is possible to prepar specimens that provide the necessary conditions fo testing the hypothesis of which the pituitary-porta vessels have been a main prop

Our thanks are due to Mr W J. Pardoe for hi help in preparing the wax reconstruction

Observation of Desert Locust Swarms by Radar

THE possibility of detecting flying locusts by radar was examined theoretically some years ago, using the deduction of Ryde[1] that the intensity of a centimetric radar echo from raindrops is proportional to ΣND^6, where N is the number of drops of diameter D per unit volume Raindrops do not exceed about 6 mm in diameter , and recorded rainfall intensities indicate that there can rarely be more than ten such drops per cubic metre in the heaviest precipitation. More than half the weight of a locust is water , from considerations of water-content alone, a swarm averaging ten flying locusts per cubic metre, as recorded in the Kenya Highlands in 1945 [2], with each locust containing about 1 c c of water, might be expected to give an echo of intensity at least an order of magnitude greater than that given by the very heavy precipitation considered , and it was concluded that recognizable echoes might well be given by much more attenuated swarms Subsequent field-work[3,4] has suggested that considerably lower volume densities, of the order of 0 1 locust per cubic metre, are in fact more representative of even the denser parts of flying swarms , densities of this order, however, might still be expected to give echoes comparable with those given by heavy precipitation

Radar equipment was known to be in regular use in the determination of upper winds at a series of meteorological stations within the invasion area of the desert locust (*Schistocerca gregaria* Forsk), and an approach was accordingly made in 1950 to the Meteorological Office, through the Anti-Locust Research Centre. The co-operation of the Air Ministry stations concerned was at once offered by the Meteorological Office, with the comment that, since the back-scattering of the radiated energy is largely a surface phenomenon, results were likely to be somewhat better than would be indicated by considerations of water-content alone At the same time it was pointed out that a type of radar giving plan-position-indicator form of presentation would be more suitable for observing locusts than the *GL* III equipment in use at the meteorological stations concerned.

The first radar sighting of a locust swarm was in fact recorded at 17 00 G M T (20 15 local time) on March 22, 1954, at lat 28° 50′ N , long 49° 30′ E , in the Persian Gulf about midway between Bushire and Kuwait, by H.M S *Wild Goose* A naval centimetric combined air- and surface-warning radar set was used, with a tilted parabolic cheese aerial. The locusts appeared to constitute a swarm of at least 15 miles radius, and were detected at ranges up to sixty miles, over a sector of up to 80°, giving large 'fluffy' echoes on a plan-position-indicator, similar to the effects of mechanical jamming Flying locusts were seen at the time in the light of a 10-in signalling projector, and dead ones were seen next morning floating on the sea, at a density estimated at about a thousand locusts over 40,000 sq. yd This confirmation of the earlier theoretical conclusion opens up possibilities of securing new information on the structure, density and movement of flying swarms which come within range of suitable radar installations, especially from photographic records of the echoes observed , such data are likely to be of particular value in the further development of aircraft methods of attacking flying swarms[3]

The locusts concerned were mature (yellow) desert locusts, and were recorded as moving very slowly southwards The wind was light and variable at the time, following a spell of moderate north-westerlies over the northern Persian Gulf during March 21 and the morning of March 22 (data provided by Chief Meteorological Officer, Middle East Air Force) The locusts represented in all probability one of a number of mature swarms which had been present since late February in the Kuwait area, about a hundred miles to the west and north-west of the position of the ship report

The time of the radar sighting was two hours after sunset and three-quarters of an hour before moonrise , and the report is of considerable interest as evidence of flight in swarm formation in darkness and over the sea, when visual reactions might be expected to have been minimal and auditory reactions[5] may well have been involved in maintaining swarm cohesion The air temperature recorded at the time at the ship was 69° F , which is several degrees lower than has previously been recorded during the night flight of desert locusts on such a scale[6] Most of the locusts, flying higher than the level of the ship, are, however, likely to have been experiencing temperatures above 69° , radiosonde observations from Bahrein Island recorded temperatures of 80° at 1,600 ft at 14 30 G M T the same day and 78° at 950 ft at 02 05 the following morning, respectively 7 deg and 11 deg above the corresponding surface temperatures[7]. The establishment of such a temperature inversion over the Persian Gulf is usual during March[8]

The co-operation of the Royal Navy, the Meteorological Office, and the East African Meteorological Department is gratefully acknowledged.

Widespread Diurnal Variations of Effective Slope of the Ionosphere

OVER a period of twelve months, measurements have been made at Seagrove Radio Research Station of the bearing and elevation angles of radio signals received from two transmitting stations at about the same distance but in directions differing by almost 90° from the receiving station From these measurements the effective slopes of the ionosphere have been found to be related at places about 1,500 km apart, and the average diurnal variation of these slopes has been measured.

The measurements were made on the rotating interferometer situated at Seagrove, Auckland[1], and refer to the horizontally polarized component of the incoming wave The equipment is such that the observed incoming angle is that of the particular wave which gives the greatest output from the horizontal multiple-loop aerials employed

The two transmitting stations chosen for this investigation were *ZQD*, Nandi, Fiji, on 9,315 kc /s, distant 2,000 km almost magnetically north, and *VLQ*9, Brisbane, Queensland, on 9,660 kc /s, distant 2,250 km almost magnetically west

The measured angles were averaged over each hourly period and then over as many days as possible in each month.

Let $\delta(x)$ be the measured elevation angle for station x, $\Delta(x)$ the elevation angle for station x which would have been measured in the presence of a horizontal ionosphere, $\theta(x)$ the measured bearing angle for station x, $\Theta(x)$ the great circle bearing, measured east of north, $\psi(NS)$, $\psi(EW)$ the effective slopes of the ionosphere about north–south and east–west lines as axes the slope angle being measured from the horizontal and regarded as positive for an increasing height towards the north or east

Then, if the angles of arrival may be assumed to occur as the sum of the various ionospheric effects, we have

$$\begin{aligned} \delta(ZQD) &= \Delta(ZQD) + \psi(EW) \\ \delta(VLQ9) &= \Delta(VLQ9) - \psi(NS) \\ \theta(ZQD) &= \Theta(ZQD) - k\,\psi(NS) \\ \theta(VLQ9) &= \Theta(VLQ9) - k\,\psi(EW), \end{aligned} \tag{1}$$

where k is a factor depending on the geometry of the transmission paths

From the measured angles it has been possible to choose some months during which conditions over the two paths were similar enough for $\Delta(ZQD)$ and $\Delta(VLQ9)$ to be considered identical (except for a small constant factor arising from the small difference in path-length) Under these conditions, it can be seen from equations (1) that a plot of $\{\delta(ZQD) - \delta(VLQ9)\}$ as a function of $\{\theta(ZQD) + \theta(VLQ9)\}$ defines straight line of slope $-1/k$ In Fig 1 the exp mental results averaged over the months July (19 and March, April and May (1954) have been plot in this way The times shown against the poi refer to local time at the mid-point of the path points lie on a line of slope $-0\ 5$ during the d time, but the points for night-time indicate that assumption of equality of $\Delta(ZQD)$ and $\Delta(VLQ9)$ not then valid

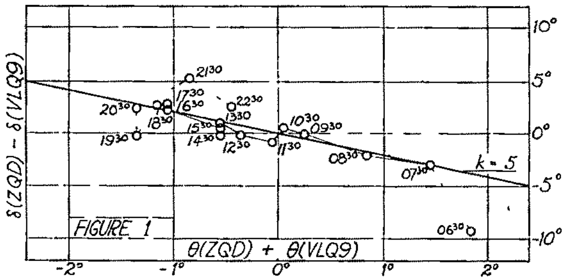

FIGURE 1

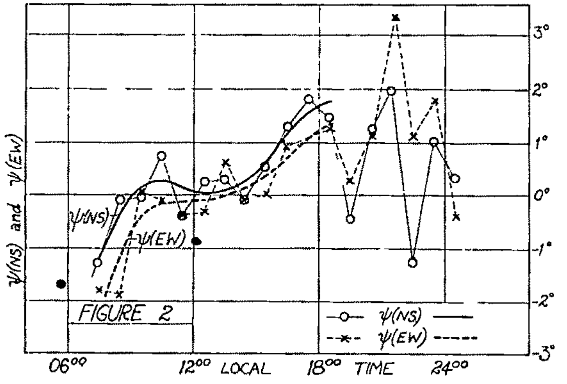

FIGURE 2

Using the experimental value of $k = 0\ 5$, effective slopes of the ionosphere may be fou since (apart from some constant factors),

$$\begin{aligned} 2\psi(NS) &= \delta(ZQD) - \delta(VLQ9) - \{\theta(ZQD) - \theta(VLQ9)\} \\ 2\psi(EW) &= \delta(ZQD) - \delta(VLQ9) + \{\theta(ZQD) - \theta(VLQ9)\} \end{aligned}$$

$\psi(NS)$ and $\psi(EW)$ have been plotted in Fig from equations 2 using the same experimental resu as before The heavy full and dotted lines show smoothed day-time behaviour

The Seagrove Radio Research Station is opera by the Physics Department, Auckland Univers College, and receives a grant from the New Zeala Department of Scientific and Industrial Resear The work briefly described above is to be publish more fully elsewhere

Radio Astronomy in Hawaii

SINCE early 1953, observations of cosmic sta have been made at an altitude of 10,020 ft. from t top of Haleakala volcano on the island of Maui the Hawaiian archipelago near lat. 20° N. A Lloy mirror technique is used with frequencies near 30, 50 and 100 Mc /s The anomalies introduced the ionosphere at the first three frequencies are great that most of the results are unintelligib At 100 Mc /s the situation is sufficiently simple be partly understood Sources with discontinuit of surface brightness small compared to a minute arc produce rapid interference patterns Smo sources of larger angular width produce much slow diffraction patterns The hours of darkness prov the best results During the day, radiations from t sun stir up the topmost parts of the atmosphere above the *F*-layer. This situation manifests its as great absorption, probably due to scatteri especially during the afternoon hours Thus there a marked diurnal effect. This diurnal effect is le on far northern sources and increases rapidly magnitude and duration as sources of lower decl tion are observed Obviously, there is also an azimu effect

During the present part of the solar activity cy the background intensity of the sun is very consta from day to day and month to month Also t azimuth of the sun changes with the seasons. Wh farthest north at the summer solstice, quite acce able and reproducible diffraction patterns a secured If a very small bright source is also prese a faint interference pattern may be riding alo on top. With the advance of the seasons, the s moves south and the results depreciate. The fa interference patterns disappear, the diffraction p rn gets weak, sunrise appears late and is not distinct y the time the autumnal equinox arrives the solar attern is merely incoherent fluctuations having a eriod of 3–20 min with an amplitude less than a nth that present near the summer solstice As us is being written, the sun has faded out altogether ear the horizon and can only be detected through e high secondary lobes of the antenna The best cplanation of these observations seems to be that iere is a great bulge in the outer parts of the earth's mosphere approximating to a thick disk perhaps)° or 40° wide When looking out to the north, one oserves through a thin and relatively transparent gion As the source moves farther south, the line sight has to traverse a longer path through the urbulent scattering region, and less energy arrives a more incoherent state at the observer The situaon at sunset is similar to that described above, ccept that the phenomena are more complex due the presence of well-developed E- and F_1-layers hich are usually absent at sunrise It seems profitble to follow up these observations at other freuencies

The outstanding sources in Cassiopeia and Cygnus ill show interference patterns at 100 Mc /s Both oparently are of considerable asymmetry because e rising and setting patterns are different This uation is particularly marked in the case of issiopeia, which produces an excellent compound terference pattern on rising but only a diffraction ttern on setting The details of these studies will described elsewhere They are supported by the esearch Corporation

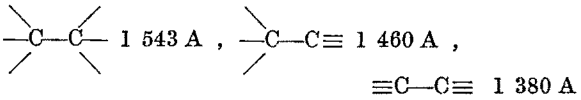
Carbon–Carbon and Carbon–Hydrogen Distances in Simple Polyatomic Molecules

A DEPENDENCE of bond distances on environment is first noticed when the carbon–carbon single-bond stance in methyl acetylene was compared with at in ethane[1]. In recent years, a wealth of material sed mainly on infra-red and microwave spectra[2] s confirmed this dependence Still more recently, e study of high-resolution rotational Raman ectra has supplied further data (partly unpublished) this dependence It is the purpose of this comunication to review briefly the results of the work carbon–carbon and carbon–hydrogen distances

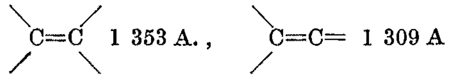
A number of compounds have now been investigated which, similar to methyl acetylene, a carbon–carbon igle bond is adjacent to a triple bond In all these ses, the C—C distance comes out to be close to at originally found for methyl acetylene, namely, 460 ± 0 003 A, whereas in ethane and in diamond, iere all adjacent bonds are single, the C—C distances 1 543 A [3] and 1 54447 A [4], respectively The result the  distance appears to be largely dependent of whether the atom attached to the ple bond is carbon or nitrogen It was first shown Pauling, Springall and Palmer[5] by means of ectron diffraction that the C—C distances in diacetylene and dicyanogen, with a triple bond on each side of the C—C bond, are even smaller than in methyl acetylene and similar compounds More precise values have more recently been obtained by Vallance Jones[6], Westenberg and Wilson[7] and Møller and Stoicheff[8] The average, again independent of whether carbon or nitrogen is attached to the triple bond, is 1 380 ± 0 002 A Thus we have the series



1 543 A , 1 460 A , ≡C—C≡ 1 380 A

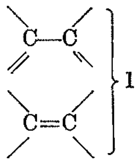
The decrease from the second to the third distance is approximately the same as from the first to the second

The carbon–carbon double-bond distance in ethylene is well known to be 1 353 A, as shown by Gallaway and Barker[9] One of us (B P S, unpublished) has recently obtained the rotational Raman spectra of light and heavy allene (C_3H_4 and C_3D_4), in which there are two adjacent C=C bonds The spectra give for the carbon–carbon distance 1 309 A, a value that is appreciably lower than that of a C=C bond surrounded by single bonds only A similar though less accurate value has been obtained by Johnson and Strandberg[10] for ketene (CH_2CO) Thus we have



1 353 A., 1 309 A

Recently, from the rotational Raman spectrum, Stoicheff[11] has obtained a precise value of the carbon–carbon distance in benzene, namely, 1 397 A This value corresponds to a mixture of a single bond adjacent to two double bonds and a double bond adjacent to single bonds Unfortunately, the former is not yet known separately However, we may write



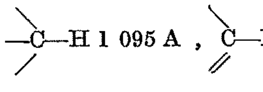
1 397 A

For comparison, the carbon–carbon triple bond distance is

—C≡C— 1 207 A,

a value that is surprisingly independent of the type of atom attached to the single bonds In particular, in methyl acetylene[12], cyanoacetylene[7], and dimethyl triacetylene[13] (X-ray diffraction), the triple bond maintains its normal length in spite of the fact that the adjacent C—C single bond has apparently borrowed some strength from the triple bonds, that is, is considerably reduced in length One might have expected that the triple bond in these compounds would be longer than normal

The carbon–hydrogen distance also depends on the environment, as has been pointed out before[14], but the dependence is not as strong as for the carbon–carbon distances. Using recent data, we have



—C—H 1 095 A , C—H 1 07₁ A., ≡C—H 1 065 A.

Of these values, that for ≡C—H is an equilibrium internuclear distance, whereas all other values quoted here are r_0 values, that is, they include zero-point vibration The value for $\equiv$C—H is probably the most accurate, that for $\overset{\diagdown}{\underset{/\!/}{\mathrm{C}}}$H the least accurate. For benzene, which might have been expected to give a value similar to ethylene, Stoicheff[11] found 1 084 A. Slightly different values for the C—H distance in methane are obtained, depending on which isotope is chosen, but they are within a few thousandths of the value given

Similar differences have been found by several authors[15] for the C—Cl, C—Br, C—I bonds, depending on whether they are adjacent to a triple bond or single bonds. But in these cases, unlike those discussed above, there is also a dependence on the adjacent atoms. A clear case of this kind is the $\overset{\diagdown}{\underset{/}{—\mathrm{C}}}$—F bond which, in methyl fluoride[16], has the length 1 385, in fluoroform 1 332 A [17]. However, in the case of the C—C, C=C, C$\equiv$C and C—H bonds, the effect of adjacent atoms on the bond-length seems to be small compared to the effect of the adjacent bond-type

Corrosion Fatigue of Low-Alloy Chromium–Molybdenum Steel as affected by the State of Heat Treatment

MANUEL has shown[1] that the spheroidized zones which exist on each side of a weld in plain carbon steel are a source of accelerated corrosion in oil-well drilling tubes

Modern hollow mining-drill steel rods possess such a spheroidized zone near the shank end. The rods are manufactured from as-rolled material, the shank end being austenitized, quenched and tempered. Thus there exists in the rod a short section containing spheroidized carbide, which occurs at the junction of the as-rolled body and the heat-treated shank. This zone can be distinguished by a marked 'valley' in a hardness traverse carried out along the rod, l etching and by micro-examination

Approximately 95 per cent of mining-drill ste rods in use at Kalgoorlie have the following cor position carbon 0 97 per cent, chromium 1 15 p cent, molybdenum 0 25 per cent, silicon 0 20 p cent, manganese 0 25 per cent

In a group of fifty fractures of such rods whi has been examined here, it was observed that fracture occurred at the point of lowest hardne (the fully spheroidized section) where fatigue failu would be expected to occur The fatigue limit of t steel with fully spheroidized carbide was estimat from tensile test results to be 66,500 lb. per sq However, in the case of thirty-seven of the fractur failure occurred at the point where spheroidizat was just beginning, the stepped surface of the failures pointing to corrosion fatigue The fatig limit of this structure was estimated from tens test results to be 107,300 lb. per sq in. The sour of failure in each case was at the central hole

A ferroxyl accelerated corrosion test was carr out on a scale-free shank containing a spheroidiz zone, illustrated in Fig 1 (above) It was observ that marked accelerated corrosion occurred at t spheroidized zone, as shown in Fig 1 (below) Th zone was thus more anodic than any other poi on the surface, the internal hole acting as cathode this test

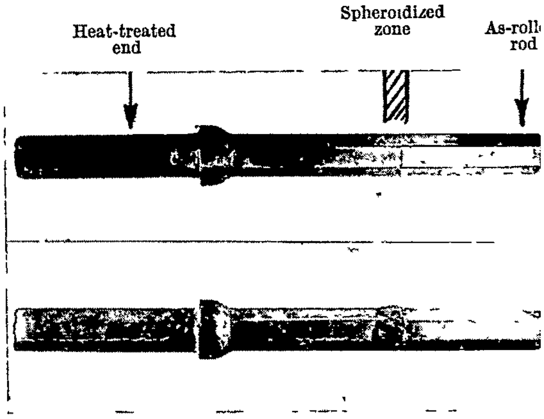

Fig 1 *Above* Shank end of drill steel, showing the junctio between as-rolled rod and the heat-treated end, at which th spheroidized zone occurs

Below Same shank as above, after immersion for seven day in ferroxyl reagent The adhering band is of agar jell containing the complex ferrous-ferricyanide ion This ban marks the highly anodic region which corresponds to th spheroidized zone above

In practice, accelerated corrosion occurs at spheroidized zone from the internal hole, the flush water in this hole acting as electrolyte The corros pits produced then act as stress concentrators, a failure occurs by corrosion fatigue.

Further work is proposed to investigate the eff of heat treatment on the rate of corrosion of ste covering a range of compositions, the tests includ loss of weight and electrode potential measureme of samples with various structures

A Light Condenser for Spectrographical Purposes

THE luminosity of a transparent light source, such s a fluorescent liquid, can be intensified by the rinciple of superposition[1] We have devised an ntensifying device for spectrographical purposes pplicable directly to a light-emitting tube

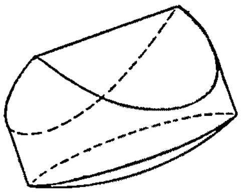

Fig 1

Two special prisms P_1, P_2, each of which is a ombination of a right-angled prism and a convex ens, having an axis of symmetry (Fig 1), are set t a distance apart from each other, the lens surfaces ace to face, with the axes on the same line, and the wo edges parallel to each other (Fig 2) Let the radii f curvature R_1, R_2 of the lens surfaces L_1, L_2, the istance between them l, and the distances d_1, d_2 etween the edges and the lens surfaces in the espective prisms, be limited by the following conditions for convenience sake (1) $R_1 = R_2$, (2) $d_1 =$ ${}_2$, (3) the foci on both sides of the lens systems ${}_1$, L_2 fall on the two edges E_1, E_2 of the prisms espectively

It is most important to make the angle of ${}_1$ exactly 90°, and the angle of P_2 $90° - \varepsilon$, where is a very small angle

Though in practice excitation of light is taking lace in the space between L_1 and L_2, to make the xplanation easier we assume for the moment a light ource on the plane S, which contains E_1 and is erpendicular to the common axis, and is imagined o be in the prism substance It will be shown later hat the imaginary source has an effect equivalent o the actual one in this case From the light pencil mitted from a point Q on S in the direction of P_2, e take the ray $Q(1)$, which is parallel to the axis, 1) being the point at which the ray falls on the lens urface L_1

Though the ray $Q(1)$ passes on and goes through ${}_2$, a ray which comes infinitesimally close to $Q(1)$ nd on the nearer side to the axis falls first on the otal reflecting plane T_2' and then on T_2, and when t comes back again to the surface L_1, it strikes the oint (2) which is nearer to the axis by $2\varepsilon d_2 + 2\varepsilon ln$ han (1), where n is the refractive index at L_2 As n the prism P_1 the ray advances parallel to the xis, it falls on S at the point Q', which is also nearer to E_1 by $2\varepsilon d_2 + 2\varepsilon ln$ than Q Of the light pencil emitted from Q as imagined above, that half which is on the nearer side of $Q(1)$ to the axis (let us call this an inside half-pencil) becomes a parallel beam in P_2, and suffering total reflexion twice, by T_2' and T_2 successively, it returns to P_1 and converges to Q' on S Thus the image of Q made by the inside half-pencil is Q', which is $2\varepsilon d_2 + 2\varepsilon ln$ nearer to the edge than Q But actually, before it converges to Q' the pencil returns once more to P_2 by total reflexions at T_1 and T_1', just as it starts from the point Q'', which is symmetrical to Q' with reference to the neutral plane It will be noticed that the restarting pencil is inside, the converging one to Q' being outside Now the position is the same as the starting point, and the next image of Q'' is formed on S and $2\varepsilon d_2 + 2\varepsilon ln$ nearer E_1 than Q''

If we make a narrow plane S_1 perpendicular to the axis, by removing the edge E_1, it is clear that the circulating half-pencil comes at last to intersect this plane S_1, and is superposed here on the direct beam If in practice excitation of light is taking place in the space between L_1 and L_2, the effective imaginary pencil starting from Q passes perfectly through the emitting space, and we can thus substitute a real pencil for the assumed one within the meaning of geometrical optics On the other hand, successive images of Q made by the outside half-pencil arrive on S farther and farther from the axis, and we can never collect them

Next, we calculate the total luminosity I_t given by inside half-pencils at S_1 If we denote the luminosity of the direct beam coming through the window L_1 and S_1 by I, and the rate of intensity loss during one circulation by r, I_t is given by

$$I_t = 2\{I + (l - r)\, I + (l - r)^2\, I + \quad .\}$$

in which the term number is given in the most favourable case ($2\,\varepsilon d_2 + 2\varepsilon ln = b$) by $\frac{A}{2}\Big/b$, where A is the aperture of L_1 and b the breadth of S_1 The factor $\frac{A}{2}$ arises from the fact that a pair of symmetrical points on S gives a perfect beam through S_1, and that the actual rays emitted between L_1 and L_2 give, on one hand, a pencil diverging from Q, and on the other, converging to the point

If we neglect absorption loss, we are only concerned with the reflexion losses at L_1 and L_2 Let us assume $r = 16$ per cent, considering a case of emission from a gas, then

$$I_t = 2I\ \{1 + \frac{84}{100} + \left(\frac{84}{100}\right)^2 + \left(\frac{84}{100}\right)^3 + \quad \}$$

If we make b sufficiently small compared to A, we can take as an approximation the infinite series, and

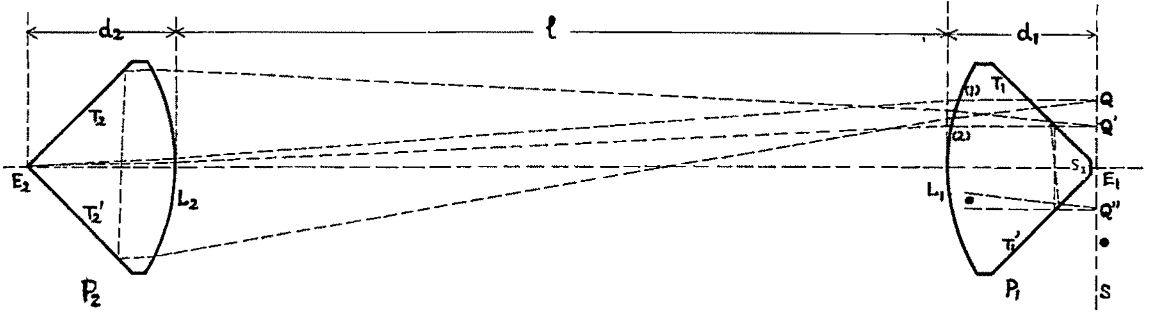

Fig 2

$$I_t = 2I \frac{1}{1 - \frac{84}{100}} = 2 \times \frac{100}{16} I = 12I.$$

But when the emitting substance is a liquid, we can generally expect a larger intensification owing to a smaller r Generally speaking, a high refractive index of the prism substance is required at T_1, T_1', T_2 and T_2' to make the reflexions perfect, whereas at L_1 and L_2 a low value is preferable to make r small It is very difficult to make the prism angles exactly correct With our discharge tube, on the ends of which the two special prisms are stuck, ε is somewhat smaller than the value calculated, and the value of I_t was only $7I$

Uniform Field Breakdown in Air

RECENT work by Llewellyn Jones and Parker[1] on the steady-state current flow in a uniform field gap in air subjected to a steady d c potential has been interpreted in terms of the Townsend theory of breakdown involving a secondary or γ-process Oscillographic observation, however, shows that, as the breakdown voltage is approached, relatively high current pulses of short duration occur. It can be shown that these pulses, both in amplitude and frequency of repetition, do not conform to the Townsend theory, and this suggests that another mechanism is involved

It can also be shown that, when a high value of series resistor is included in the circuit, it is in theory virtually impossible to reach the Townsend criterion for breakdown Experimentally, however, no difficulty is experienced in causing a breakdown under these conditions.

The application of stochastic methods to the Townsend theory of breakdown shows that, even if the secondary process is assumed to be the fastest possible, that is, entirely photoelectric in nature, the calculated formative time-lags are longer than those observed experimentally[2] and that the discharge would be diffuse Experimentally, the discharge is observed to be filamentary

Further, the velocity of observable luminosity across the gap, on the Townsend theory, is slower than the experimentally observed velocity by a factor of about 10^4

The above evidence suggests that in addition to the Townsend mechanism, a streamer-like mechanism is also involved in the breakdown of the uniform field gap in air for values of $pd \sim 500$ mm. Hg cm. The best agreement with the available experimental evidence appears to be obtained by postulating that the current build-up due to the Townsend primary and secondary processes provides conditions favourable for the initiation of the streamer. The streamer then moves across the gap and causes the breakdown to be completed Such a postulate also provides a single theory to explain the breakdo of gaps of different geometry, the geometry decid the manner in which the critical conditions f streamer initiation are established.

On the above mechanism, it can be shown th the existence of a secondary process is not essent to cause breakdown, and that the failure of so experimenters to detect a secondary process is therel explained.

A full discussion is being prepared for submissi elsewhere. This work was done during my ten of an I.C I. research fellowship, which is grateful acknowledged

Preparation of Solid Solutions of Free Radicals at Room Temperature

ORGANIC free radicals can be produced by irradi tion with ultra-violet light of molecules held in transparent rigid medium at low temperatures[1,2]. T method consists in dissolving a suitable substance, in a solvent which forms a transparent glass freezing. The solution is cooled to the temperatu of liquid nitrogen and exposed to ultra-violet ligl After a time it becomes coloured, and optical absor tion spectroscopy shows that free radicals have be created. These radicals persist until the glass warmed so as to lose its rigidity Such radicals m be formed in several ways, but the simplest of the is 'photo-oxidation'[1]—the ejection of an electron fro the illuminated molecule, D. We restrict ourselv to those substances which form radicals only by tl process. It seems that the high viscosity of t glassy solvent prevents the recombination of t resulting radical ion, D^+, and the ejected electro

The use of solutions at the temperature of liqu nitrogen is not always convenient, so we ha investigated the possibility of producing free radic at room temperature Instead of using a solve which freezes to a glass, we tried to create fr radicals in a medium which is glass-like at roo temperatures and which, moreover, can be form without heating A solid solution in transpare methyl methacrylate plastic (I C I 'Perspex') w used, and this was illuminated at room temperatu Such a solution was prepared as follows so N,N'-tetramethyl *p*-phenylenediamine ('Wurste base', $(CH_3)_2N\,C_6H_4\,N(CH_3)_2$), which is known form free radical ions by photo-oxidation, w dissolved in chloroform, and mixed with a liqu solution of 'Perspex', also in chloroform. The flu was then poured on to a glass plate and the chlo form evaporated, leaving a thin film behind. Aft illumination at room temperature for 5 min. wi ultra-violet light from a high-pressure mercury lam the film turned brown It was shown by means paramagnetic resonance[3] that free radicals were n present in the film A sample was made by fold the film into a pellet, and a single paramagne resonance absorption line was found, a few gauss width and with $g = 2\ 001 \pm 0\ 002$, which is typi of a free radical. The dependence of the resonance absorption on temperature was similar to that of Wurster's radical ion, $(CH_3)_2N\,(C_6H_4)\,N(CH_3)_2^+$, the intensity of the absorption rising to a maximum near 200° K [4].

Films of pure 'Perspex' showed no paramagnetic resonance after illumination with ultra-violet light

The experiment was repeated with a solution of *p*-phenylenediamine, $NH_2\,C_6H_4\,NH_2$, which also forms free radical ions by photo-oxidation, though less easily than Wurster's base After 25 min illumination, the film became coloured, brown at the edges and grey-green in the centre Paramagnetic resonance showed that free radicals were present in the film, the concentration being greater in the grey-green part

The radicals produced in this manner are rather stable. Paramagnetic resonance of about the original intensity was found after the illuminated film had been kept for a month at room temperature After ten months, however, paramagnetic resonance could not be detected, although the film remained coloured It is noteworthy that, though these substances deteriorate in air, a sufficient number of molecules survive the film-making process to give a reasonable yield of free radicals.

The use of a thin film allows the formation of free radicals throughout the sample, even by quanta corresponding to wave-lengths where the absorption of the 'Perspex' becomes appreciable (less than about 3,000 A) These radiations will, however, be able to pass through such a thin film Furthermore, a thin transparent film should be convenient for optical measurements, and this technique should be useful for studying free radicals which are normally unstable

We are indebted to the University of Oxford for the award of a Pressed Steel Co , Ltd , research fellowship (D. B), and to the Department of Scientific and Industrial Research for a maintenance grant (A. C R.-I) during the tenure of which these researches were carried out

Solubility of Oxygen in Water

In a recent communication, Truesdale and Downing[1] reported that the values for the solubility of oxygen in de-ionized distilled water, determined by the Winkler[2] method, were significantly lower than the standard values commonly employed[3] They gave a new empirical equation valid in the range 0–40° C , relating the solubility and the temperature

In connexion with some investigations on the salting-out of oxygen in aqueous electrolytes a number of determinations of the solubility of oxygen in distilled water at 25° C were made over a period of several months The Winkler method, modified to the extent that 0 01 *N* thiosulphate instead of 0 025 *N* usually recommended was employed and, as in the case of the authors mentioned, air freed from carbon dioxide and saturated with water vapour was used In the experimental arrangement the air was drawn slowly through the water until equilibrium was established

The results obtained at 25° C. in five series of determinations gave values, corrected for pressure, in the range 8 07 ± 0 05 p p m. The equation of Truesdale and Downing yields at 25° C a value of 8 11 p p m , while the figure quoted in "Standard Methods"[3] is 8 38 p p m. The present results are an independent confirmation of the results recently reported and underline the need for a revision of the 'standard' values

Oxygen Exchange between Nitrous Acid and Water

THE exchange of oxygen atoms between nitrous acid and isotopically enriched water has been followed by the isolation of the nitrous acid as its insoluble silver salt, and the decomposition of this salt, to water, by heating with dry ammonium chloride *in vacuo*. The water produced was then equilibrated with carbon dioxide, and the isotopic content of this gas determined mass spectrometrically

The work of Hughes, Ingold and Ridd, and Schmid (summarized in ref 1), showed that under appropriate conditions the active nitrosating agent in diazotization was dinitrogen trioxide, N_2O_3, formed by the reaction

$$H_2N^+O_2 + NO^-_2 \rightleftharpoons N_2O_3 + H_2O , \qquad (1)$$

but that under somewhat different conditions the reagent was either the nitrous acidium ion, $H_2N^+O_2$, or the nitrosonium ion, N^+O, derived from it.

Any of these entities, or all, could give oxygen exchange between nitrous acid and water, by reaction (1), by the hydration of the nitrosonium ion (2), or by the reaction between water and the nitrous acidium ion (3)

$$N^+O + H_2O \rightleftharpoons H_2N^+O_2 \qquad (2)$$

$$H_2{}^{18}O + H_2N^+O_2 \rightleftharpoons H_2N^+O^{18}O + H_2O \qquad (3)$$

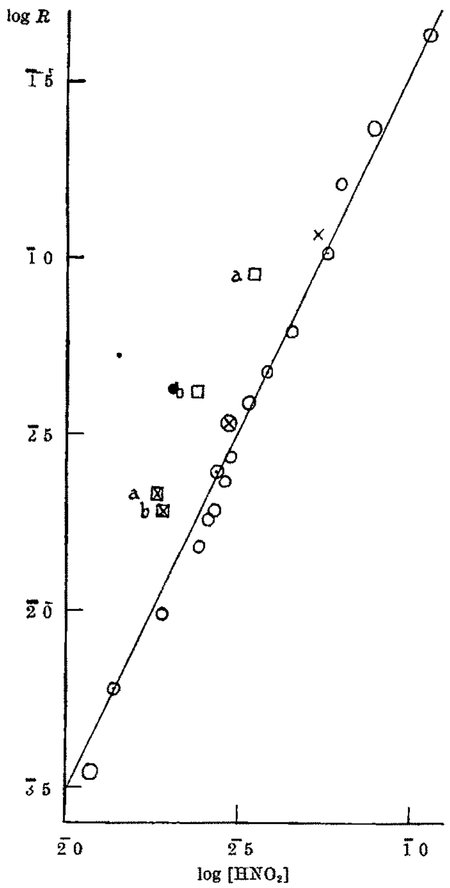
A distinction between some of these mechanisms can be made by following the dependence of exchange-rate on the concentration of nitrous acid It can readily be shown that exchange by reaction (1) will follow the kinetic law

$$\text{Rate} = k_2\,[HNO_2]^2,$$

where $[HNO_2]$ is the concentration of molecular nitrous acid , but that reactions (2) and (3) will give

$$\text{Rate} \propto [H^+]\,[HNO_2]$$

To allow the isolation of sufficient material for our isotopic analysis method, a solution of sodium nitrite (concentration varying between 0 4 and 1 *M*) was used, and to this was added not more than one-fifth the equivalent of perchloric acid. Under these conditions we can assume the concentration of molecular nitrous acid to be given by the stoichiometric



Dependence of exchange-rate on concentration of nitrous acid in absence and presence of other ions ○, no added ions, ⊗, [NO_3^-], 0 529 *M*, ×, [ClO_4^-], 0 445 *M*, ⊡, [Cl^-], (*a*) 2 36 *M*, (*b*) 2 31 *M*, ⊠, [Br^-], (*a*) 1 265 *M*; (*b*) 1 067 *M*

concentration of perchloric acid, after correcting for the initial decomposition of the nitrous acid

The relation between exchange-rate and concentration of nitrous acid is plotted logarithmically in Fig 1, and the straight line is drawn with a slope of 2 This clearly shows the dependence of exchange-rate on $[HNO_2]^2$, and the results do not fit the kinetic forms of reactions (2) and (3) We are able to show that under our conditions the addition of even high concentrations (*c.* 0 5 *M*) of sodium perchlorate and nitrate have no very marked effect on the exchange, but that the halide ions Cl^- and Br^- enhance the rate of exchange, presumably by the reaction

$$H_2N^+O_2 + X^- \rightleftharpoons NO - X + H_2O$$

(where X = Cl,Br), a reaction which is known to play a part in the halide ion catalysis of diazotization[1].

It is instructive to compare the values which we observe for k_2, the second-order rate coefficient for oxygen exchange with respect to HNO_2, with the second-order rate coefficient for diazotization under conditions in which the rate is independent of amine concentration The value of k_2 for oxygen exchange is 32 mol l $^{-1}$ min $^{-1}$, and that for diazotization (private communication, Hughes, Ingold and Ridd) is 40 mol. l $^{-1}$ min $^{-1}$ (this latter value is somewhat dependent upon the value taken for the dissociation constant of the nitrous acid, whereas the corresponding rate-coefficient for oxygen exchange is independent of this constant); we have calculated the diazotization-rate using the value of 3 2 × 10^{-4} mol. l.$^{-1}$, at 0 for the dissociation constant[2]. The agreement b tween these rates is reasonably close, particularly view of the widely differing reagent concentratio used (the diazotization experiments were carried o with reagent concentration *c* 10^{-3} *M*, private com munication, Hughes, Ingold and Ridd)

If we assume an exchange mechanism, under o experimental conditions, involving attack of nitrit ion on the nitrous acidium ion, we can use the dat of the halide ion catalysis to calculate the reactiviti of chloride and bromide ions, relative to nitrite io taken as unity, towards the nitrous acidium ion th values are Cl^-, 0 38, Br^-, 0 46. The value f bromide ion is, as expected, greater than for chloride and is comparable with the value of 0 54 obtaine by the measurement of bromide-ion catalysis diazotization (Hughes, Ingold and Ridd, privat communication) In the exchange measurements n correction has been made for any ionic strengt effect caused by the added halide ions

It is probable that at higher acid concentration the nitrite ion concentration will be reduced sufficiently to allow exchange by reactions (2) and (3 with a consequent change of kinetic form.

We are indebted to Profs E D Hughes and C. K Ingold, and to Dr. J H Ridd, for their advice an for their prior communication of their diazotizatio results

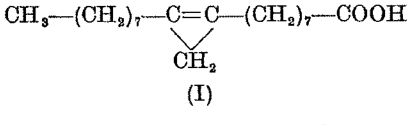
Structure of Sterculic Acid

The structure of sterculic acid, the major component of the kernel oil of *Sterculia foetida*, ha attracted the attention of various workers Hilditc *et al* [1] failed to isolate the acid but concluded fro the constants of the oil and the mixed methyl ester and some degradative experiments that it wa 12-methyl octadeca-9 11-dienoic acid Steger an Van Loon[2], working on the mixed fatty acids deduced that it was probably a hydroxy acid $C_{18}H_{34}O_3$ However, recently Nunn[3] has isolated th acid, $C_{19}H_{34}O_2$, by the method of urea complexes an suggested its structure as ω-(2*n*-octyl*cyclo*prop-1-enyl) octanoic acid (I)



$$CH_3-(CH_2)_7-\underset{\diagdown\;\diagup}{C=C}-(CH_2)_7-COOH \qquad \text{with } CH_2 \text{ bridging the two C}$$

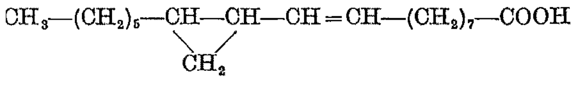
(I)

Nunn has based this structure mainly on the stron band at 9 8 μ in the infra-red spectrum of dihydro sterculic acid He has, however, not taken the infra red curve of the sterculic acid itself, and the positio of the double bond seems to have been fixed withou any supporting evidence

In this laboratory, sterculic acid has been separated from the mixed fatty acids by low-temperatur fractional crystallization in the colourless crystallin form, $C_{19}H_{34}O_2$ (m p 19°, n_D^{25} 1 4758) Its catalyti hydrogenation gives dihydro- and tetrahydro-sterculi acids, suggesting the presence of two, or the equivalent of two, double bonds

From the iodine value (98 2) and diene value (40 3), t may be inferred that these double bonds are probably conjugated, although the ultra-violet absorption spectrum does not show any band in the region 2200–3200 A The infra-red curve, however, gives clear indication of a *cyclo*propane ring at 9 96 μ and a double bond (C = C) at 6 09 μ on the shoulder of the strong carbonyl band at 5 9 μ

The *cyclo*propane ring exhibits typical unsaturation towards many specific additive reagents, as demonstrated by Kohler and Conant[4]. Therefore, the *cyclo*propane ring in sterculic acid may form a 'conjugated system' with the double bond, resulting in structure (II)



$$CH_3—(CH_2)_5—CH—CH—CH=CH—(CH_2)_7—COOH \quad (\text{bridge } CH_2)$$

(II)

Reduction and oxidation products obtained by various investigators[1,3] and also by us find ready explanation with this structure

Further, the synthesis of compound I has been effected from stearolic acid by the action of diazomethane This synthetic product gives an infra-red curve which is different from that of sterculic acid, thereby conclusively showing that the structure (I) is not correct

The details of this work will be published elsewhere

Separation of Saponins by Paper Chromatography

In the course of a study on the composition of saponins from Indian raw materials, difficulties were encountered in the complete separation of the glycosides in pure form by chemical means. The usual method of repeated precipitation with solvents is not dependable and does not ensure the chemical purity of the separated products, the more so because many of the saponins are hygroscopic

A convenient method of separation has now been developed by paper partition chromatography The spray reagent used was sodium periodate in alkaline permanganate solution, recently reported by Lemieux and Bauer[1] for the detection of carbohydrates, this has been found to be satisfactory in the case of saponins, giving permanent brown spots against a white background.

Qualitative characterization of the fairly pure saponins[2], isolated in this laboratory, was carried out on Whatman No. 1 filter-paper by the ascending method[3] with the system *n*-butanol – acetic acid – water (4 1 5) for 10–24 hr, and the dried papers were sprayed with a freshly prepared solution of sodium meta-periodate in alkaline potassium permanganate solution The papers were left for an appropriate time (5–6 min.) before they were washed with running water, when distinct brown spots of saponins appeared against the almost white background of the paper On drying, these spots remained unchanged for an indefinite period

Table 1

Saponins isolated from	No of saponins isolated by chemical method	No of saponins as shown by chromatography	R_F values
Entada scandens (Gila)	2	2	(1) 0 246 (2) 0 386
Balanites roxburghii (Hingora)			
Balanites roxburghii pericarp	1	1	0 202
Balanites roxburghii kernel	1	2	(1) 0 215 (2) 0 312
Sapindus trifoliatus (Ritha)	1	1	0 222
Bassia latifolia (Mahua)	1	1*	0 203

* One distinct spot and two indistinct spots on the strip

The R_F values found for the respective saponins are shown in Table 1 By employing this method, it has been possible to show that the saponins, purified by the usual chemical procedure, are in some cases actually composed of more than one saponin. Other solvent systems are being examined Details will be published elsewhere in due course.

Techniques for labelling Trees with Radioactive Phosphorus

Insects feeding on plants in nutrient culture solution have been labelled with tracer-levels of radioactive isotopes in studies of insect feeding-habits[1] and insecticidal action[2]. Such insects have also been released in the field for population studies[3], and others fed on labelled artificial diets have been used in the study of insect metabolism[4].

To investigate the movement of the mealybug vectors of swollen shoot disease of cacao, techniques were studied for obtaining radioactive trees for the subsequent labelling of insects at their feeding sites under field conditions The artificial release of labelled insects in the field is unsatisfactory for such investigations

By the first method a panel of bark was removed from the stem of *Abutilon* sp. and 1 5 mc of phosphorus-32 in a volume of 3 ml held in a 'Plasticine' cup was introduced laterally through the severed conducting vessels After 24 hr, leaves 4 ft above the area of introduction provided 300 counts/min /sq cm, and after 48 hr nymphs of *Dysdercus* sp feeding 5 ft above the place of injection provided 12–346 counts/min This technique has been used successfully in translocation studies with dyes[5], and the resulting mechanical damage to the tree is small The amount of radiophosphorus translocated is uncertain because of the high residual activity on the 'Plasticine' cup. With high levels of activity, this technique presents some radiation hazard in the field Fig 1 shows that

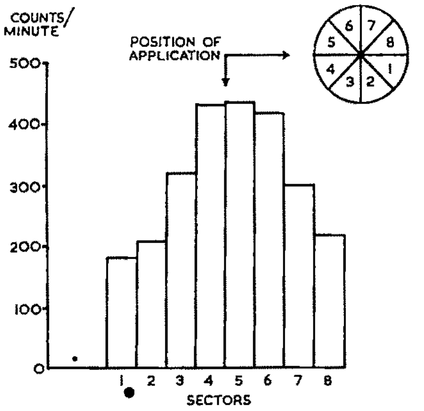

Fig 1 Activity distribution on the cross-section of the trunk of *Abutilon* sp 1 ft above the position of application

fourteen days after application the activity remained localized on that side of the stem at which the radiophosphorus was introduced

In the second method, 5 mc of phosphorus-32 in 10 ml. of solution was introduced through a glass tube sealed with 'Picine' wax into a small hole at the base of a young *Syringa vulgaris* L Fig. 2 shows the activities recorded from 1 5 cm leaf disks cut on the main veins of opposite leaves 4 ft above the point of introduction and 24 hr. after uptake of the active solution. The distribution of activity within the tree was very localized, but adult mealybugs (*Planococcus citri* (Risso)) fed for seven days on young shoots gave counts of 13–42/min. This technique produces little mechanical damage to the tree, but minor leakages are difficult to eliminate. The efficiency of this technique may undoubtedly be improved by the methods employed for diagnosing mineral deficiencies[6,7]

By a third method, 1 mc in 0 7 ml and 9 mc in 1 5 ml of solution of phosphorus-32 was introduced into two Douglas firs (*Pseudotsuga taxifolia* (Poir) Britt) by trunk implantation Such techniques have been used in studies with systemic insecticides[8] Th glass ampoules containing the active solutions we inserted into 1-in holes in the trunks and were the broken within the trees by knocking in tight-fitti wooden plugs Eight days after implantation, tot activities were recorded on the cut ends of 2-f lengths of trunk at various elevations (Table 1 Activities were also recorded on the trunk surfa of the tree implanted with 9 mc (Table 2), th was not possible with the tree implanted with 1 mc but 15 counts/sec were recorded at the tips of later branches at about 15 ft above the ground.

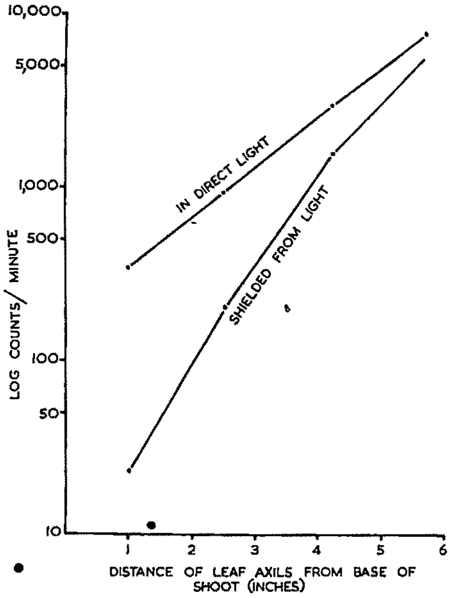

Fig 2 Activities from 1 5 cm diameter leaf disks cut on the main veins of opposite leaves of a young shoot of *Syringa vulgaris* L 24 hr after the introduction of 5 mc of phosphorus-32

25	5	2	2	4
Growing tip, ≏ Bg	Tips of lateral branches, 0–80			

≏ Bg = counts approximating to background-level (3 counts/sec

In both trees it was estimated that about 95 p cent of the activity remained at the position implantation Table 1 indicates the localization activity at certain levels and in certain branches the main trunk Table 2 indicates a marked localiz tion on one side of the trunk, particularly so at t 9–11 ft level, at which region there is a decrease total activity recorded on the cut ends It is eviden therefore, that at this level the path of translocatio approaches the surface of the trunk and that high measurements result from a decrease in absorptio thickness of the wood

The trees appeared normally healthy at the tin of felling. This technique reduces radiation haza in the field to a minimum The sizes of hole an ampoule do not permit the use of large volumes active solution or phosphate carrier which mig assist in translocation from the position of implantation.

The methods described are suitable for obtaining radioactive host plants of insect populations in the field All three techniques suffer from two disadvantages, namely, the translocation of phosphorus-32 from the point of application is small and the distribution of tracer within the tree is localized Similar results were obtained with calcium-45 and rubidium-86 injected into yellow birch[9] Future investigations will be directed towards methods of root application and the use of carriers to aid in tracer distribution Autoradiography will be used to elucidate the pattern of distribution within the conducting tissues

These experiments were initiated when I was at the Isotope School, Atomic Energy Research Establishment, Harwell, and I wish to thank Mr. R A Faires, of the School, for much valuable advice and help , also Dr Leyton, at the Forestry Department, Oxford, and Dr Scott Russell, Department of Agriculture, University of Oxford, for their interest in the work. This communication is published with the consent of the Director of the West African Cacao Research Institute, Gold Coast

Acceleration of Citrate Oxidation in Yeast by Aspartic Acid

CITRATE oxidation in cell-free extracts of *Saccharo-yces cerevisiae* has previously been reported to be timulated by a weakly basic factor present in boiled east juice[1] It was afterwards observed that mmonia accelerates citrate oxidation when added o the assay system for oxidation factor, and sig-ificant amounts of free ammonia were found in the oiled juice prepared from the D C L commercial akers' yeast investigated[2] In a further study of ifferent strains of yeast, high oxidation factor ctivity has now been observed in ammonia-free xtracts of Anheuser–Busch commercial bakers' east when added to a particulate-free enzyme from he same organism In these preparations all activity s due to free L-aspartic acid, present in a concentra-ion of 4 6 μM/gm yeast The end-product of citrate xidation in the presence of aspartic acid is glutamic cid The reaction requires the addition of di- or tri-yridine nucleotide coenzymes This is illustrated n Fig 1

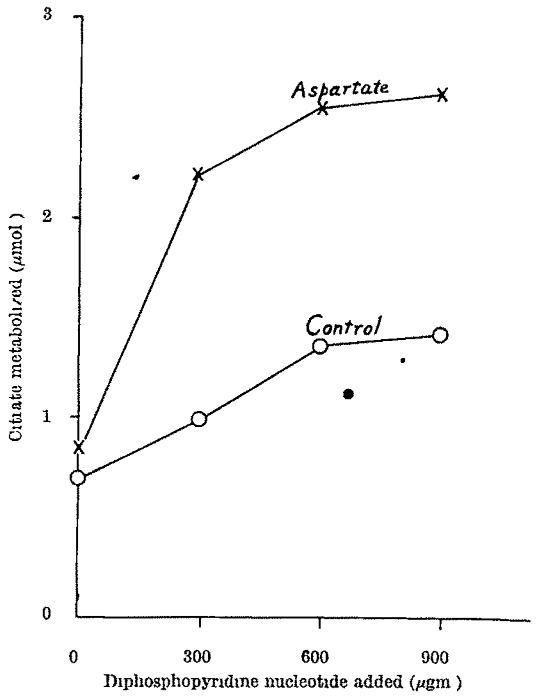

Fig 1 Dependence of the aspartate reaction on coenzyme Tube contents 4 μM citrate, 50 μgm magnesium, 0 3 ml enzyme dialysed 24 hr against 0 1 M potassium phosphate, pH 7 1, at 0° C , final vol 1 0 ml Incubation, 30 min at 37° C 2 μM L-aspartate added as indicated In the presence of excess di-pyridine nucleotide, 0 4 μM glutamate was formed in the control, and 2 2 μM in the presence of aspartate

Excess coenzyme does not inhibit the increased itrate oxidation in the presence of aspartate (aspart-te reaction) This clearly distinguishes the effect f aspartate in yeast from the effect in certain mam-nalian systems where aspartate can be shown to accelerate citrate oxidation by increasing the turnover of reduced coenzyme

The yeast enzyme actively catalyses the transamination reaction

$$\text{Aspartate} + \alpha\text{-oxoglutarate} \rightleftharpoons \text{oxalacetate} + \text{glutamate} \quad (1)$$

Any α-oxoglutarate formed from citrate in the presence of aspartate would react to form glutamic acid This reaction, however, cannot explain the stimulation of citrate oxidation by aspartate, as the breakdown of citrate to α-oxoglutarate is irreversible in the present system Nor do either aspartate or α-oxoglutarate affect any of the following enzymes involved in citrate oxidation aconitase, the *iso*citric dehydrogenases specific for di- and tri-pyridine nucleotide, and oxalosuccinic carboxylase The latter enzyme in all respects resembles the enzyme from pigeon breast muscle studied by Ochoa and Weisz-Tabori[3]

Further evidence against the participation of reaction (1) in the aspartate reaction is presented in Table 1

Table 1 CONDITIONS AS FOR FIG 1 L-GLUTAMATE (20 μM), OXALACETATE (5 μM) ADDED AS INDICATED

Additions	Citrate metabolized (μM)
—	1 47
Aspartate	2 73
Glutamate	1 33
Glutamate and aspartate	2 57
Oxalacetate	1 08
Oxalacetate and glutamate	3 07
Oxalacetate and aspartate	1 08

An excess of glutamic acid sufficient to prevent reaction (1) from proceeding to the right has no appreciable effect on the aspartate reaction Glutamate + oxalacetate simulate the effect of aspartate, presumably by giving rise to aspartate The strong inhibitory action of oxalacetate would be expected on the basis of reaction (1) or any other transamination reaction of aspartate.

In agreement with previous results[4], the aspartate reaction, like other transaminations, is inhibited by high concentrations of cyanide. Pyridoxal phosphate causes no stimulation. The nature of the transamination involved in the aspartate reaction remains unknown. Ammonia, which activates citrate oxidation in both the D.C.L. and the Anheuser–Busch strains of yeast, probably acts by a mechanism similar to the aspartate reaction.

Distribution of Adrenaline and Noradrenaline in the Adrenal Medulla

In previous papers[1], I have described two histochemically different types of chromaffin cells in the adrenal medulla of the rat. Adrenal medullas of several species have now been studied using the same histochemical methods, and adrenaline and noradrenaline determinations made[2]. The presence of brightly fluorescing cell groups against a dark background of non-fluorescing medullary cells was a constant finding in formalin-fixed sections of the adrenals of most species. Table 1 shows the proportions covered by fluorescing islets and the percentage amounts of noradrenaline in adrenal medullas of different species. Good correlation between the islet content and the noradrenaline content is obvious.

Table 1

Species	Noradrenaline content (% of both catechols)	Fluorescing tissue (% of whole medulla)
Cat	35–60	*c.* 50
Dog	20–40	*c.* 40
Hamster	25–40	*c.* 30
Mouse	15–35	*c.* 25
Rat	10–20	*c.* 15
Guinea pig	5	+?
Rabbit	3	0

In order to study the effect of adreno-medullary stimulation, male rats were injected subcutaneously with insulin (0·6 I.U./100 gm. body-weight at 9 a.m., the same dose at 12 o'clock, killed at 4 p.m.), or with nicotine (*c.* 1 mgm./100 gm. body-weight, killed ½–24 hr. later). Chronic overdosage of nicotine was caused by injecting 2–4 mgm. of nicotine daily for about 6½ months; these rats were killed about two weeks after the last injection. The results are summarized in Fig. 1, which shows that insulin causes a selective depletion of adrenaline and disappearance of the chromaffin reaction from all but some medullary cells, which form islets closely similar to the fluorescing islets. The fluorescence of these islets was not affected by insulin. After a single injection of nicotine, on the contrary, a selective loss of noradrenaline and disappearance of fluorescing and chromaffin materials from the 'islet' cells were observed. However, the response was somewhat variable. Prolonged treatment with nicotine caused a medullary hyperplasia associated with a pronounced increase in the relative amount of fluorescing medullary tissue and in the noradrenaline content. All these observations suggest that the two kinds of medullary cells bear specific relations to the storage and secretion of the two kinds of adreno-medullary hormones, a view already put forward in the earlier papers[1].

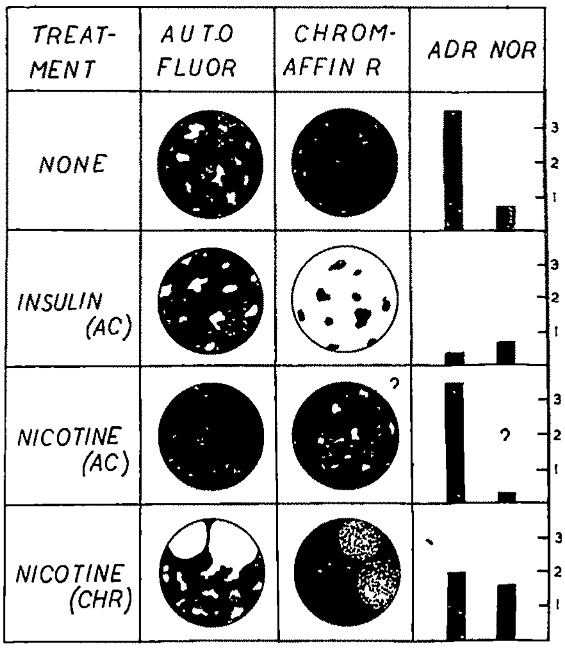

Fig. 1. Schematic illustration of the effects of insulin and nicotine on the histochemistry and catechol amine content of rat adrenal medulla. Distribution of fluorescing substances in the formalin-fixed sections is indicated in white; chromaffin materials are shown as black. The heights of the columns on the right refer to adrenaline and noradrenaline concentrations, expressed as per cent of dry medullary tissue. *AC* = acute; *CHR* = chronic.

The problem was investigated more directly in the cat and the hamster. Serial sections were prepared of fresh-frozen glands. Every other section was fixed in formalin and examined for the distribution of the fluorescing islets, and the alternate sections were freeze-dried. Information obtained from neighbouring formalin-fixed sections was used to dissect small pieces of the freeze-dried sections with variable proportions of fluorescing tissue. A piece with much fluorescing tissue always contained a higher proportion of noradrenaline than a piece with little islet tissue, taken from the same section. Small amounts of noradrenaline were nevertheless regularly found in pieces supposed to contain no fluorescing cells. The fluorescing islets were too small to allow mechanical separation of pieces containing exclusively fluorescing cells. Pieces with *c.* 70 per cent of islet tissue were found to contain approximately the same proportion of noradrenaline.

The observations indicate that some adreno-medullary cells contain much adrenaline and little noradrenaline, whereas other cells—which can be demonstrated by fluorescence microscopy of formalin fixed sections—contain predominantly or exclusively noradrenaline. The fact that noradrenaline forms a strongly fluorescing, poorly water-soluble substance with formalin, which adrenaline does not, suggests at formalin fixation is a kind of histochemical ethod for the selective demonstration of nor-lrenaline in the adrenal medulla, a point now under ore detailed study.

While this work was in progress, Hillarp and Hok-:t[3] described a technique for histochemical demon-ration of noradrenaline With this technique, using ffered potassium iodate, they also came to the nclusion that the two medullary catechol amines e stored in two different kinds of cells

I am grateful to Prof J H Gaddum and to Di. aithe Vogt for their guidance and laboiatory cilities during the academic year 1952–53, which I ent in the Department of Pharmacology, University Edinburgh

Cyanide-resistant Mitochondria from the Spadix of an *Arum*

Highly active preparations of mitochondria have en obtained from the spadix of *Arum maculatum*[1] iese exhibited the ability to oxidize acids of the :ebs's cycle and pyruvic acid in their presence No rrier needed to be added and the terminal oxidase sponsible for the oxidations was not identified The spiration of slices of spadix is not inhibited by anide[2], even though it is very rapid, with Q_{O_2} rising 31 8. As mitochondria are generally supposed to omote respiratory oxidations through their con-ned cytochromes, the reaction of these aroid tochondria to cyanide is of obvious interest

Using the method of Hackett and Simon, we were le to prepare mitochondrial suspensions of high tivity The extraction and suspension medium ntained 0 05 *M* phosphate buffer, *p*H 7 1, 0 2 *M* :rose, and 0 001 *M* magnesium sulphate, before ygen uptake was measured, 0 0004 *M* adenosine phosphate was added Endogenous respiration in is medium was virtually nil in all preparations ldition of citrate, α-ketoglutarate or succinate at)2 *M* concentration caused rapid uptake of oxygen)02 *M* Pyruvate in the presence of 0 002 *M* malate s also oxidized

After two hours incubation at 20° C the contents the manometer flasks containing no substrate and th α-ketoglutarate added were examined for acid mation by paper chromatography 1-ml aliquots m each were deproteinized with 2 volumes of ianol, and the dried supernatants, after acidifying th hydrochloric acid, were extracted with six lots 10 ml of ether The ether extracts were run two-dimensional chromatograms using ethanol-ammonia and mesityl oxide – formic acid as solvents[3]. After spraying the dried papers with bromo-phenol blue, no acids could be detected in the control experiment, but large amounts of citrate, malate succinate and fumarate had been formed during the incubation with α-ketoglutarate, as shown in Fig 1 All the α-ketoglutarate added had been oxidized

ble 1 1 ml Mitochondrial Suspension = 2 gm Fresh Weight of Tissue Total Volume, 30 ml T = 20° C

Substrate	Oxygen uptake (µl) in 15 min	Hydrogen cyanide added
Nil	0	—
Citrate	150	151
α-Ketoglutarate	293	(291)
Succinate	388	365
Pyruvate + malate	115	—

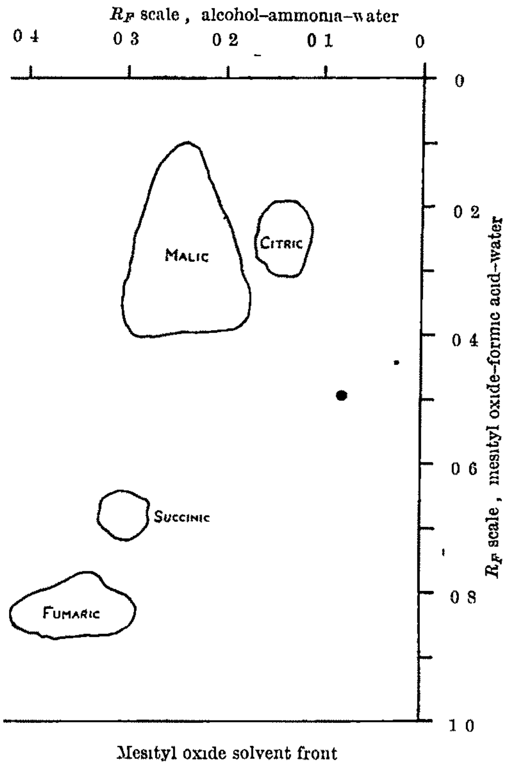

Fig 1

Addition of 0 001 *M* hydrogen cyanide with the substrate caused no inhibition of oxygen uptake in the presence of citrate or succinate during the first 15 min. There was no inhibition in the presence of α-ketoglutarate, and the pattern of acid formation was not changed either, but here the cyanide would probably be removed as cyanhydrin of the keto-acid present in large excess

After longer periods partial inhibition slowly developed in the presence of succinate After two hours it amounted to about 60 per cent, but by this time the rate in the control sample had itself fallen away considerably In the presence of citrate no inhibition or slowing down had appeared after 55 min

These experiments appear to confirm the suggestion that the mitochondria of *Arum* spadix are able to catalyse a Krebs's cycle of reactions, but they also indicate that at least some of the oxidations on which it is based are not inhibited by 0 001 *M* cyanide The partial inhibition that develops slowly in the presence of succinate is very different from the rapid and complete inhibition of the usual metallic oxidases

Chelated Iron Compounds for the Correction of Lime-induced Chlorosis in Fruit

LIME-INDUCED chlorosis of fruit trees is a serious problem on calcareous soils in Great Britain, and until recently the only practical means of correcting this disorder was a combination of grass cover and trunk injection of iron salts. The injection method is laborious, transient in effect and often causes severe damage to the trunk, especially to *Prunus* species Soil treatment with iron salts has not been effective owing to precipitation of iron in the soil

A new approach to the problem followed the discovery by Jacobson[1] in 1950 that ferric dipotassium ethylenediamine-tetraacetate (Fe-EDTA) was a satisfactory source of iron for plants growing in culture solutions at high *p*H In 1952 Stewart and Leonard[2] showed that 10–20 gm of chelated iron per tree (as ferric dipotassium ethylenediamine-tetraacetate) would control iron chlorosis (copper-induced) of citrus trees growing in acid soils Under alkaline conditions, as much as 100–300 gm of chelated iron per tree was necessary to control lime-induced chlorosis[3] The authors considered that such large amounts might render the method impracticable for field use

Recently, two new chelating agents for trivalent iron have been described by Chaberek and Bersworth[4] They are N,N′-dihydroxyethylethylenediamine-diacetic acid (HEEDDA) and N-hydroxyethylethylenediamine-triacetic acid (HEEDTA) The iron chelates of these two acids, together with that of diethylenetriamine-pentaacetic acid (DTPA), have been shown by Wallace *et al* [5] to be more effective in correcting lime-induced chlorosis of ornamental trees than ferric dipotassium ethylenediamine-tetraacetate

In 1953 small-scale field-trials were started by us to test the effect of ferric disodium ethylenediamine-tetraacetate, as soil dressings and foliage sprays, on lime-induced chlorosis in red currants, plums and pears Rates of soil dressings were based on the early work of Stewart and Leonard (*loc cit*) for citrus in acid soils These rates proved ineffective under the alkaline soil conditions The foliage sprays showed promise and no damage occurred on plum and red currant at concentrations of 0 1 per cent or less An account of these preliminary trials has been given by Bould[6]

Further experiments were made in 1954 on pe and plum growing in a highly calcareous soil of p 7 8, using increased rates of application of fer disodium ethylenediamine-tetraacetate as a s dressing, and also varying rates of ferric diethylen triamine-pentaacetate and ferric N-hydroxyeth ethylenediamine-triacetate For pear the chelat were applied in solution around the trees (within circle of 6 ft diameter) and thoroughly watered Soil treatments and foliage sprays were also appli to chlorotic plum trees, var Burbank's Giant Prun The ferric-ethylenediamine-tetraacetate was broadc on April 6 around the trees, within a circle of 12 diameter, at the rate of 16 oz per tree (avera height 12 ft and girth 12 in) and lightly watered the ferric N-hydroxyethylethylenediamine-triaceta was applied in a similar manner at 12 oz and 16 per tree

Foliage sprays of both these salts and also of fer diethylenetriamine-pentaacetate, at 0 1 per ce concentration plus a wetting agent, were applied plums on three successive occasions at petal-f and after two fortnightly intervals

At another centre one foliage spray of fer diethylenetriamine-pentaacetate, at 0 1 per ce concentration plus a wetting agent, was applied extremely chlorotic peach trees on June 29

The treatments, rates of application, and effec on chlorosis and extension growth of pear are sur marized in Table 1 Ferric disodium ethylenediamin tetraacetate and ferric diethylenetriamine-pent acetate at 8 oz per tree gave a complete control chlorosis and resulted in vigorous extension growt This is the first recorded response by fruit trees Great Britain to soil treatments There was observable response to the ferric N-hydroxyethy ethylenediamine-triacetate, but it should be point out that the dressings of this compound suppli much less chelated iron than the other two, a further tests are needed

The plum trees did not respond to the s treatments This may have been due to t failure of the iron chelates to penetrate to t plum roots The chelates were not thorough watered in as for pear, and a dry period follow application

The foliage sprays on plum gave a commerc control of chlorosis, and, with the exception of fer disodium ethylenediamine-tetraacetate which pr duced a little marginal and tip scorch, caused damage

Table 1 EFFECT OF SOIL DRESSINGS OF CHELATED IRON ON THE INCIDENCE OF LIME-INDUCED CHLOROSIS IN PEAR *var* CONFERENCE O QUINCE ROOTSTOCK

Soil treatment	Amount of chelated iron (gm)	Date applied	Tree height (ft)	Tree girth (in)	Chlorosis 11–8–54	Extension growth 11–8–54
8 oz Fe-EDTA per tree	32 0	6–4–54	5½	7½	Nil	Very good
12 oz Fe-EDTA per tree	48 0	6–4–54	5	7	Nil	Very good
4 oz Fe-HEEDTA per tree (absorbed on vermiculite)	3 4	6–4–54	4½	7½	Severe with necrosis	Poor–medium
6 oz Fe-HEEDTA per tree	5 1	6–4–54	4	5½	Very severe with necrosis	Poor–medium
8 oz Fe-HEEDTA per tree	6 8	6–4–54	4½	5	Medium–severe	Medium
Controls	—	—	—	—	Very severe with necrosis	Poor–medium
4 oz Fe-DTPA per tree	11 4	11–5–54	5	5½	Slight	Medium
6 oz Fe-DTPA per tree	17 1	11–5–54	4½	5	Trace	Good
8 oz Fe-DTPA per tree	22 8	11–5–54	6	7	Nil	Very good
Controls	—	—	—	—	Very severe	Poor
45 ml Fe-HEEDTA per tree (liquid)	1 6	2–6–54	5	5½	Very severe with necrosis	Very poor
75 ml Fe-HEEDTA per tree	2 6	2–6–54	5½	5½	Medium severe	Poor
150 ml Fe-HEEDTA per tree	5 3	2–6–54	6	5½	Severe	Poor
200 ml Fe-HEEDTA per tree	7 0	2–6–54	6	5½	Medium severe	Good
Controls	—	—	—	—	Very severe	Very poor

Three weeks after applying a single foliage spray of
ric diethylenetriamine-pentaacetate to peach trees,
e chlorosis had almost completely disappeared and
e leaves have remained green until the present
te

These results indicate that control of lime-induced
n chlorosis in fruit trees is possible by soil treat-
nt, providing sufficient iron chelate is used and it
transported to the absorbing roots by rain or heavy
tering The cost of adequate soil dressings of
elates may prove uneconomic on a commercial
le for certain fruit crops For plums and peaches
e foliage spray method appears to give a satis-
ctory control of chlorosis, during the season of
plication, at a much lower cost Pear leaves are
re difficult to wet and they are damaged more
sily than plum, apple and peach

The full results of these and of further experiments
ll be reported elsewhere

Acarine Disease of the Honeybee and Temperature

IT has been suggested from time to time that there
ay be relationships between acarine disease of
neybees and weather or other environmental
ctors, but such a view has also often received
rongly reasoned opposition, as by Phillips[1] and
orgenthaler[2], and no reliable relationship with a
ather factor has so far been forthcoming

I have now found that if the areas between January
otherms for 27° F and 54° F actual temperatures
the northern hemisphere are shaded, upon a map
the world, and areas between July isotherms for
° F and 66° F are shaded the other way upon the
ap, the two sets of shadings are found in super-
sition in Britain and adjacent parts of Europe,
d the doubly shaded areas correspond fairly closely
ith the main areas in Europe in which acarine
sease is found Over the rest of the world (using
e corresponding July and January isotherms
spectively in the southern hemisphere) such overlap
curs only in a few limited areas One of these
eas is in Argentina, in which country acarine
sease has been found In North America—reported
have no acarine disease—there is no overlap except
a very limited area on the extreme west Asia, in
ost areas substantially without acarine disease, and
frica and Australia, from which the disease has not
en reported, show only very small localized areas
overlap

The theory is advanced that acarine disease is
und only where overlap of these two temperature
nds occurs, and that the areas where the two bands
oss most centrally (as in Britain) are the areas of
ghest infestation New Zealand shows marked
erlap, particularly in the south, and on this theory
uld harbour acarine disease if it were introduced, though so far the disease has not been reported from that country

It is suggested that the action of high summer temperature in reducing the disease incidence is probably based on the faster working and shorter life-span of the worker bees which obtains under the more favourable foraging conditions, and which gives the mite less time to reach maturity and migrate from bee to bee, the low summer limit apparently coincides rather closely with the temperature limit for effective survival of the honeybee colony itself The action of low winter temperature in reducing the incidence of disease may be partly due to the disturbed state of a diseased winter cluster, rendering it less able to survive the severe conditions of a cold winter, while the high winter limit may be principally a reflexion of the relatively high summer temperature which, for physical reasons, in temperate zones, apparently almost always accompanies it

Many significant direct correlations between acarine incidence and temperature have been obtained in the course of this work, for example, a coefficient of $-0\ 50$ (50 degrees of freedom, $P < 0\ 001$) for acarine disease and summer temperature in fifty-two counties in England and Wales on data by Butler[3], and a coefficient of $+ 0\ 51$ (20 degrees of freedom, $P < 0\ 02$) for acarine disease and winter temperature for twenty-two years on data for Britain by Morison[4], as well as highly significant correlations between incidence of acarine disease and January–July temperature-range, on either Butler's or Morison's data taken separately, and also between acarine disease and suitably selected phenological criteria on either of the above sets of data It has been found that the above correlations with summer and winter temperatures can be drawn together mathematically into a single working hypothesis, which in operation corresponds closely with the overlap of the isotherm ranges suggested above

Calculations based on this hypothesis, using temperatures prevailing in Britain in the appropriate years, agree with the timing of the severe epidemic of acarine disease in Britain between about 1904 and 1919, as well as the reduction in its incidence (evident in Morison's data) at the present time They are also in agreement with the higher incidence of acarine disease in Scotland than in England (also seen in Morison's data) and, when calculations are based on temperatures in Switzerland, with the much lower incidence in that country (Morgenthaler[5]) The calculations show that at the temperatures of the major areas of North America, Africa and Australia, as well as most of Asia, the disease, on this hypothesis, would be unable to maintain itself

I wish to thank Principal M A H Tincker and Dr G D Morison, of this College, for encouragement, Dr F H C Marriott, of the University of Aberdeen, for statistical advice, and Dr C B Williams, of the Entomological Department, Rothamsted Experimental Station, for constructive criticism Further details of this work will be published in due course

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

ASSISTANT EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER (with a degree in chemistry or physics or the N D D T) IN THE TECHNICAL CHEMISTRY DEPARTMENT, for work on the manufacture and analysis of milk powders and evaporated milk—The Secretary, Hannah Dairy Research Institute, Kirkhill, Ayr (January 15)

JUNIOR ASSISTANT CHEMISTS (with a B Sc degree or equivalent, and preferably with some experience in fuel technology) in the Central Laboratories, South-Eastern Gas Board, 709 Old Kent Road, London, S E 15—The Personnel Manager, South-Eastern Gas Board, Katharine Street, Croydon, quoting V 28/488 (January 15)

LECTURER IN THEORETICAL PHYSICS—The Registrar, The Ur
sity, Reading (January 17)

LECTURER/SENIOR LECTURER (preferably interested in undert
genecological or cytogenetic studies on the Australian flor
BOTANY, at the University of Sydney, Australia—The Secre
Association of Universities of the British Commonwealth, 5 G
Square, London, W C 1 (Australia, January 19)

SCIENTIFIC OFFICER, Grade I (with a university degree of
standard in physics or equivalent qualifications, and preferably
experience in optical instrumentation) in the Department of Su
High-Speed Aerodynamics Division, Aeronautical Research
oratories (Instrumentation Section), Salisbury, South Australia
the development and design of general physical and particu
optical instruments for aerodynamics research—The Senior Repres
tive (A P 23), Department of Supply, Australia House, St
London, W C 2 (January 20)

PHYSICIST (with a good honours degree in physics or equiv
professional qualifications, and preferably with some experien
research and field experiments), at the Central Research Estal
ment, Isleworth, Middlesex, to carry out research on strata stud
The National Coal Board, Establishments (Personnel), Hobart H
Grosvenor Place, London, S W 1, quoting TT/900 (January 2

EXPERIMENTAL OFFICER or ASSISTANT EXPERIMENTAL OFF
(with G C E advanced level in two scientific subjects or equiva
and ability to write clear, concise English and preferably with
knowledge of European languages) in the Department of Scie
and Industrial Research Food Investigation Headquarters, Cambr
for editorial duties on a journal of scientific and technical abst
and reviews on food science and technology—The Ministry of La
and National Service, Technical and Scientific Register (K), 26
Street, London, S W 1, quoting G 444/54A (January 22)

EXPERIMENTAL OFFICER (with a knowledge of organic chem
or biochemistry) IN THE DEPARTMENT OF INSECTICIDES AND FU
CIDES, to assist in the study of the mode of action of insectici
The Secretary Rothamsted Experimental Station, Harpenden, I
(January 22)

LECTURER (with a good honours degree in mechanical engine
or equivalent qualification, and practical experience in industry
in teaching) IN MECHANICAL ENGINEERING—The Principal, W
and District Mining and Technical College, Wigan (January 24)

ORGANIC CHEMIST (with an honours degree in science with org
chemistry as a major subject, and some postgraduate research
perience) IN THE DIVISION OF FOOD PRESERVATION AND TRANSP
Commonwealth Scientific and Industrial Research Organiza
Homebush, N S W , Australia, for investigations, with a small g
of chemists, on chemical reactions occurring on processed foods
during storage and on the chemical composition of the natural
ducts—The Chief Scientific Liaison Officer, Australian Scien
Liaison Office, Africa House, Kingsway, London, W C 2, quo
300/151 (January 29)

RESEARCH OFFICER (chemist) (with an honours degree in chemi
and preferably with research experience in the field of organic c
istry) IN THE BIOCHEMISTRY UNIT, Wool Textile Research Laborato
Commonwealth Scientific and Industrial Research Organiza
Melbourne, to develop specific reagents for the chemical modifica
of proteins and to study the effect of such reagents on the chen
and physical properties of wool keratin—Chief Scientific Lia
Officer, Australian Scientific Liaison Office, Africa House, Kings
London, W C 2, quoting 462/76 (January 29)

RESEARCH OFFICERS or SENIOR RESEARCH OFFICERS IN THE (
RESEARCH SECTION, Commonwealth Scientific and Industrial Rese
Organization, Sydney, Australia, for (*a*) to undertake investigat
of the chemical structure of Australian coals and assessment of
potential value to the chemical industry and, in particular, to exa
the behaviour of coals in various chemical reactions such as hy
genolysis or to study the chemical reactions occurring during
pyrolysis of coals (Ref 480/150), (*b*) to participate in the activ
of a group concerned with the studying of the mechanical prope
of coal and their industrial significance (Ref 480/153), and (
participate in studies being undertaken to evaluate combustion c
acteristics of Australian coals (Ref 480/154)—Chief Scientific Lia
Officer, Australian Scientific Liaison Office, Africa House, Kings
London, W C 2 (January 29)

ENTOMOLOGIST IN THE DEPARTMENT OF ENTOMOLOGY of the W
Agricultural Research Institute—The Registrar, The Univer
Adelaide, South Australia (January 31)

PROFESSOR OF EDUCATION at McGill University, Canada—
Secretary, Association of Universities of the British Commonwea
5 Gordon Square, London, W C 1 (January 31)

RESEARCH SCHOLAR IN THE DEPARTMENT OF CHEMISTRY—
Secretary, The University, Aberdeen (January 31)

SCIENTIFIC OFFICER, CHEMIST (with a first- or second-class hon
degree in chemistry or in a biological subject with chemistry a
additional subject, or equivalent qualification), at the Brown T
Research Laboratory Pitlochry, to be a member of a small t
investigating chemical problems of freshwaters, working in c
association with Biologists—The Establishment Officer, Scottish H
Department, Room 364, St Andrew's House, Edinburgh 1 (January

SENIOR LECTURER IN ZOOLOGY at the University of the Witwat
rand, Johannesburg, South Africa—The Secretary, Associatio
Universities of the British Commonwealth, 5 Gordon Square, Lon
W C 1 (South Africa, January 31)

SENIOR LECTURER IN ENGINEERING, a LECTURER IN PHYSICS,
a LECTURER IN BOTANY, at Fourah Bay College, Sierra Leone—
Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Squ
London, W C 1 (February 7)

LECTURER (Grade II) IN PHYSICS, and a RESEARCH FELLOW
PHYSICS—The Registrar, The University, Birmingham 15 (Fe
ary 15)

LECTURER IN EDUCATION at the University of Hong Kong—
Secretary, Association of Universities of the British Commonwea
5 Gordon Square, London, W C 1 (Hong Kong, February 15)

LECTURER or ASSISTANT LECTURER (with special interests in gene
or genecology) IN BOTANY—The Registrar, The University, Lee
(February 19)

PERMUTIT

ION EXCHANGE MATERIALS

The use of Permutit Ion Exchange Materials in many roles distinct from water treatment, has resulted in the development of numerous new industrial processes giving improved results and lower running costs Some materials now available are —

Zeo-Karb Na. A sulphonated coal product containing both strong and weak acid groups

Zeo-Karb 215. A nuclear sulphonated phenol resin containing also hydroxyl groups

Zeo-Karb 225. A unifunctional cross linked sulphonated polystyrene resin in bead form of high capacity and exceptional chemical and physical stability

Zeo-Karb 226. A unifunctional cross linked methacrylic acid resin in bead form containing only carboxyl groups as the ion active groups

De-Acidite E. A high capacity anion exchange material of medium basicity

De-Acidite FF. A unifunctional very highly basic anion exchange resin in bead form based on cross linked polystyrene and containing quaternary ammonium groups

De-Acidite G A unifunctional weakly basic anion exchange resin in bead form based on cross linked polystyrene and containing diethylamino groups

De-Acidite H A material similar to "De-Acidite G" but containing dimethylamino groups

Bio-Deminrolit A mixed cation and anion exchange resin for demineralisation in a single column

Decalso F. A synthetic sodium aluminium silicate suitable for the separation and concentration of vitamins and hormones

Decolorite. A resin of high porosity for removing colour from solutions.

Permaplex C-10. A highly selective cation exchange resin membrane containing SO_3H groups.

Permaplex A-10. A highly selective anion exchange resin membrane containing quaternary ammonium groups

For full technical information please write to THE PERMUTIT COMPANY LIMITED Head Office and Laboratories Dept V H 92, Permutit House, Gunnersbury Avenue, London, W 4 Telephone. CHIswick 6431

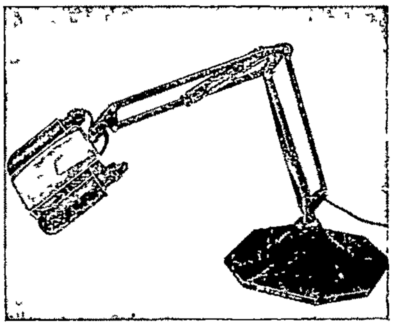
MAGNAPOISE ILLUMINATED MAGNIFIER



This new adjustable stand magnifier incorporates the well-known Anglepoise patented fittings, and brings adequate magnification and illumination to finger-tip command Its uses—like its angles—seem limitless

With the flick of a finger the lens is placed anywhere at any angle, in a position to "stay put" Here is a magnifier with adequate magnification and good field with the large rectangular lens 6″ × 3½″, combined with illumination provided by two "Pigmy" 15-watt lamps, one each side of the lens, as illustrated, and completely shielded from the viewing side, operated from mains voltage. The Magnapoise is free from sag or wobble, is unaffected by vibration, and will prove to be unsurpassed for use in the factory, laboratory, etc

Base, 11½″ across, is black featherweave finished with two adjustable arms fitted to a swivel fitting at the base, which allows every conceivable movement with perfect balance of the lens

PRICE £17 17s 0d

LECTURES AND COURSES

UNIVERSITY COLLEGE
LONDON
COMMUNICATION RESEARCH CENTRE

Free Public Lectures at 5 30 p m in the Anatomy Theatre (Entrance Gower Street) Tuesday, January 25, "The Language of Neurology, its Advantages and Limitations," Professor J Z Young Tuesday, February 15, ' A Mathematical Model of Neuronal Interaction,' Mr W K Taylor Monday, February 28, ' Translation ' Dr E V Rieu Tuesday, March 15, "The Importance of Human Communication in Industry," Professor R W Russell

Details of all public lectures (including lunch-hour lectures) from Publications Officer, University College London, Gower Street, W C 1 (Stamped envelope required)

WOOLWICH POLYTECHNIC

Special Lectures in Higher Technology and Commerce

(a) AN INTRODUCTION TO SERVO-MECHANISMS
Six lectures commencing Wednesdav, February 2 from 7 0-9 0 p m
by K B REED B Sc (Eng), A M I E E

(b) INDUSTRIAL ELECTRONICS (including Associated Laboratory Practice)
Twenty-four lectures to be held on Mondays and Wednesdays commencing January 10 from 2 0-5 0 p m
by G L BIBBY, B Sc (Eng), and K B REED, B Sc (Eng), A M I E E

(c) INSECT PESTS AND FUNGAL DISEASES IN HORTICULTURE AND MARKET-GARDENING
Twenty-four lectures commencing Thursday, February 10, from 6 0-8 0 p m
by C S WOOD-BAKER, M Sc , Ph D , F Z S , F R E S

(d) APPEARANCE IN STRUCTURAL DESIGN
Four lectures commencing Tuesday, February 1 from 7 0-9 0 p m
by P HUDSON Dip Arch A R I B A

(e) OUTLINES OF THE LAW OF PATENTS AND DESIGNS FOR EXECUTIVES
Six fortnightly lectures commencing Thursday, January 20 from 7 0-9 0 p m
by ANTHONY WALTER Barrister-at-Law

(f) RECENT DEVELOPMENTS IN INDUSTRIAL LAW
Six lectures commencing Thursday, April 21 from 7 0-9 30 p m
by E F ARAGON, Barrister-at-Law

(g) COST ACCOUNTING FOR MANAGEMENT
Eight lectures commencing Wednesday January 19 from 7 0-9 30 p m
Lecturer to be announced later

FEES Course d £1 1 0 Courses a e, f, and g £2 2 0
Courses b and c £4 4 0

ENROLMENT By personal application from 9 0 a m to 8 30 p m or by postal application to the Secretary

UNIVERSITY COLLEGE OF SWANSEA

(A constituent College of the University of Wales)
Principal J S Fulton, M A

Courses of study are provided for (a) Degrees of the University of Wales in Arts, in Pure Science and in Applied Science (Metallurgy and Engineering) (b) The training of teachers for elementary and secondary schools (c) The first medical examination of the University of Wales (d) The first year of the course for the degree of *Baccalaureus in Architectura* (e) The Preliminary Part of the scheme of study for the degree of *Baccalaureus in Pharmacia* (f) A Diploma in Social Science (g) A Diploma in Youth Leadership and Organization College courses in Pure Science are recognized by a number of medical licensing bodies as constituting a first year of medical study The College maintains a Hall of Residence for women students Entrance scholarships are offered for competition in February each year

Particulars about admission to the College in October 1955, and of the entrance scholarships, may be obtained from the Registrar University College, Singleton Park Swansea

CHELSEA POLYTECHNIC
MANRESA ROAD S W 3
DEPARTMENT OF CHEMISTRY
SESSION 1954-55
POSTGRADUATE LECTURES IN BIOCHEMISTRY

Groups III and IV of the lectures on "Biochemistry" (each group comprising five lectures) will be given by Dr E M Crook, M Sc , Ph D , and Professor F L Warren, M A , D Sc , on Mondays, 7 15 to 8 30 p m , during the period January 10 to March 14, 1955 Group III will deal with "Digestion and metabolism of proteins and amino-acids," and Group IV with ' Digestion and metabolism of lipids and sterols " The lectures are a continuation of the course which commenced in October, 1954, and are designed for students who possess a knowledge of chemistry to degree standard Fee 10s for each group

Full particulars obtainable from the Secretary

UNIVERSITY OF LONDON

A course of three lectures on "Problems of Transport in Plants" will be given by Professor W H Arisz (Groningen) at 5 30 p m on January 17, 19 and 21 at University College (Anatomy Theatre), Gower Street, W C 1

Admission free without ticket

JAMES HENDERSON,
Academic Registrar

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 *to* 64 *inclusive, or a woman aged* 18 *to* 59 *inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order,* 1952

SOUTH AFRICAN COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH
METALLURGIST RESEARCH OFFICER

Applications are invited for a post as Research Officer in the Mechanical Engineering Research Laboratory of the C S I R , Pretoria South Africa The salary scale associated with this post is £780 by £48 to £1,020 per annum In addition a cost-of-living allowance of £234 per annum is payable to married male officers Starting salary according to qualifications and experience Generous leave privileges and five-day week Candidates must be in possession of at least an honours degree in metallurgy or metallurgical engineering, or equivalent qualification The successful candidate will do research work in the field of ferrous and non-ferrous physical metallurgy The successful candidate will be required to furnish a medical certificate of good health and to become a member of the University Institutions Provident Fund The Council will bear the transportation costs of the appointee and his family from his place of residence to Pretoria Further information and application forms are obtainable from the South African Scientific Liaison Officer Africa House, Kingsway, London, W C 2

Applications, giving full details of age marital status qualifications, experience, and the names of referees must reach the Secretary/Treasurer, C S I R , P O Box 395, Pretoria, South Africa, before March 15, 1955 A copy of the application must be sent to the South African Liaison Officer in London

CENTRAL RESEARCH ESTABLISHMENT, National Coal Board (at Isleworth Middlesex) which is concerned with mining problems, invite applications for a superannuable appointment of a Physicist to carry out research on strata studies The work will be concerned initially with measurement of rock pressures Candidates should have a good honours degree in physics or equivalent professional qualifications and preferably some experience in research and field experiments Appointment will be according to qualifications and experience as either Scientist II (scale £800 by £35 to £1,150 male and £700 by £30 to £1 000 female) or Scientist III (scale £500 by £25 to £950 male and £475 by £20 to £835 female), London location allowance of £34 at the minimum rising to £82 at the maximum of the scales is payable in addition —Write giving full particulars (in chronological order) of age, education, qualifications and experience (with dates), to National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S W 1 marking envelope TT/900 Original testimonials should not be forwarded Closing date January 22, 1955

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF CHEMICAL ENGINEERING

The Appointments Committee of the Department of Chemical Engineering hope soon to be in a position to appoint one University Lecturer and two University Demonstrators in Chemical Engineering Applications will be considered from persons of broad scientific education experienced in some branch of chemical engineering physical chemistry, physics, or mechanical engineering The appointments will be subject to the Statutes and Ordinances of the University

Further particulars and forms of application may be obtained from the Secretary of the Appointments Committee of the Department of Chemical Engineering, Tennis Court Road, Cambridge, to whom applications should be sent so as to reach him by March 11, 1955

ROWETT RESEARCH INSTITUTE

Scientific Officer required to undertake research on nutrition of sheep Candidates should possess a first- or good second-class honours degree in agriculture physiology or zoology, or equivalent qualification Practical knowledge of sheep husbandry is not essential Salary scale £445 to £815 with initial placing according to experience Superannuation under F S S U

Applications, stating date of birth and particulars of qualifications and experience, together with the names of three referees, should be addressed to the Secretary Rowett Research Institute, Bucksburn, Aberdeenshire

---

BATTERSEA POLYTECHNIC

LONDON S W 11

Applications are invited from honours graduates of a British university with postgraduate experience in organic chemistry, for the post of Grade B Lecturer Salary £621 or £633 by £25 to £928, plus £30 for a good honours degree with an allowance of £18 for three years' £36 for four years and £54 for five years training and increments for industrial and research experience, less statutory deductions

Further particulars from the Clerk to the Governing Body, by whom applications should be received on or before January 28, 1955

PSYCHOLOGISTS IN THE CIVIL SERVICE The Civil Service Commissioners invite applications for nine permanent posts for Psychologists at Industrial Rehabilitation Units under the Ministry of Labour and National Service and for one temporary post for a Senior Psychologist (with permanent appointment as Psychologist) Age for the Psychologist posts at least 21 and under 31 on June 1, 1954 with extension for Regular Forces' service for the Senior Psychologist post at least 27 on June 1 1954 All candidates must possess one of the following qualifications (a) A first- or second-class honours degree of a recognized university in which psychology was taken as a main subject (b) A higher degree in psychology (c) A Bachelor of Education degree of a Scottish university or of the University of Belfast (d) A postgraduate diploma in psychology following at least two years' systematic study (e) Fellowship of the British Psychological Society (f) Associateship of the British Psychological Society (subject to certain conditions) Candidates who expect to obtain one of these qualifications shortly after the date for the submission of applications may be considered Exceptionally a candidate may be accepted if he has at least three years' responsible professional experience London remuneration (including extra duty allowance where payable) Senior Psychologist £993 to £1 328 (men) £880 to £1 161 (women) Psychologist £510 (at age 21) to £1 117 (men) £994 (women) Starting pay up to £874 (men) £847 (women) at age 30 or over on entry Promotion prospects —Particulars and application forms from Secretary Civil Service Commission Burlington Gardens, London W 1, quoting No 118/54 Application forms to be returned by February 3 1955

AIR MINISTRY REQUIRES SCIENTIFIC Officer (male) at R A F Station near High Wycombe Bucks for operational research duties theoretical studies and development work in field of communications and general electronics Qualifications First- or second-class honours degree in physics or electrical engineering or equivalent Salary Within range £467 10s to £845 Post unestablished with possibilities of establishment through Civil Service Commission whilst remaining under age 31 Opportunities for promotion to higher grade posts on staff of Scientific Adviser to Air Ministry —Application forms quoting A 109/54A from Ministry of Labour and National Service Technical and Scientific Register (K) 26 King Street London S W 1

UNIVERSITY OF CAMBRIDGE

FACULTY OF ENGINEERING

Applications are invited for four posts of University Lecturer or University Demonstrator, for one post of Assistant Director of Research and for two posts of Senior Assistant in Research The persons appointed to the lectureships or demonstratorships will be expected to have engineering experience they will be required to teach primarily in either the field of servo-mechanisms of the utilization of nuclear energy or of the strength of materials with particular reference to soil mechanics The persons appointed to the research posts will be required to work either in the field of servo-mechanisms or in that of framed structures Persons appointed will be required to take up their duties as early as possible The appointments will be subject to the Statutes and Ordinances of the University

Details of the regulations and stipends for the posts will be sent on application, inquiries should be addressed to the Secretary of the Appointments Committee, Engineering Laboratory, Trumpington Street Cambridge, and should reach him by January 21, 1955

UNIVERSITY OF LEEDS

DEPARTMENT OF COAL GAS AND FUEL INDUSTRIES WITH METALLURGY AND CHEMICAL ENGINEERING

The Council invites applications for four posts in the Department in chemical engineering, in gas engineering and in fuel technology Appointments will be made on the Lecturer scale and on the Assistant Lecturer scale (both at present under review)

Applications (three copies), stating date of birth qualifications and experience together with the names of three referees should reach the Registrar The University, Leeds 2 (from whom further particulars may be obtained) not later than January 17, 1955

UNIVERSITY OF ABERDEEN

Senior Technician required for Physiology Department, Marischal College Wage on scale £460 by £20 to £560 placing according to qualifications and experience

Applications in writing to the Secretary Marischal College

TEA RESEARCH INSTITUTE OF CEYLON

Post of Director

Applicants are advised that the closing date for the above post has been extended to January 31 1955

UNIVERSITY COLLEGE LONDON (Gower Street W C 1) requires Technician for Department of Phonetics preferably interested in acoustics, to assist in construction of electronic equipment Good holidays and pension scheme

Application forms from Secretary, quoting Phonetics/3

AGRICULTURAL RESEARCH COUNCIL require a Senior Experimental Officer in the Biochemistry Department of their Institute of Animal Physiology Salary scale £1 017 to £1,197 Superannuation under F S S U Degree or equivalent qualification and laboratory administrative experience essential, age not below 35 —Applications with names of two referees to Secretary Institute of Animal Physiology Babraham Cambs not later than January 31 1955

ELECTRONIC ENGINEER REQUIRED AT Ministry of Supply, Headquarters, London to work in branch of guided weapons directorate responsible for planning and progressing contracts with various weapons firms The officer will be required to visit these contractors during the course of his duties Qualifications Higher school certificate (science) or equivalent, but possession of degree or H N C in electrical engineering may be an advantage Knowledge of electronics required and some experience in guided weapons field would be an asset Salary within Experimental Officer range (minimum age 26) £720 to £890 per annum (women somewhat less) plus pay supplement of £30 per annum —Application forms from Ministry of Labour and National Service Technical and Scientific Register (K), 26 King Street London S W 1 quoting D 650/54A

MEDICAL RESEARCH COUNCIL REQUIRE Technician for maintenance of apparatus gas analysis etc at poliomyelitis unit at National Hospital W C 1 S T A Diploma an advantage Salary according to age and experience —Write (two referees) to Dr G Pugh, M R C Laboratories Holly Hill Hampstead N W 3

CENTRAL RESEARCH ESTABLISHMENT, National Coal Board (at Isleworth, Middlesex), which is concerned with mining problems, invite applications for the superannuable appointment of an Engineer to carry out research on instrumentation The work will be concerned with the design and development of mechanical and electromechanical instruments required for mining research both in the laboratory and underground Candidates should have good honours degrees in mechanical engineering and preferably some experience in research or instrumentation practice Appointment will be according to qualifications and experience as either Scientist II (scale £858 to £1,232 inclusive male and £750 to £1,070 inclusive female) or Scientist III (scale £534 to £1 016 inclusive male and £509 to £893 inclusive female) —Write, giving full particulars (in chronological order) of age education, qualifications and experience (with dates), to National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S W 1 marking envelope TT/902 Original testimonials should not be forwarded Closing date January 29, 1955

MINISTRY OF AGRICULTURE AND Fisheries require Scientific Officer at Tolworth Surrey, for general chemical and analytical work connected with chemical methods for the control of various animal pests and insects on stored products Qualifications Degree in chemistry or equivalent Salary according to experience, on scale £492 10s to £885 Appointment may last not more than approximately twelve months —Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K) Almack House 26 King Street London, S W 1 quoting F 679/54A Closing date January 29, 1955

APPOINTMENTS VACANT

RECENTLY QUALIFIED CHEMIST, B Sc, or A R I C age 20 to 24, required as Assistant to Head of Research and Development Department The work involves both organic and inorganic syntheses up to and including pilot plant Five-day week, canteen facilities —Write to Works Director, Thomas Morson and Son, Ltd, Wharf Road, Ponders End Middlesex

MEDICAL REPRESENTATIVES BRITISH subsidiary of leading American ethical pharmaceutical house have vacancies in several areas for Medical Representatives Good starting salary and expenses Car provided —Applications, with full particulars of age, qualifications, experience and salary required in writing only, to the Manager Pfizer, Ltd, 137-139 Sandgate Road, Folkestone, Kent

ENGINEER WANTED BY IMPERIAL CHEMical Industries, Ltd, Alkali Division, Northwich, Cheshire, to do research on industrial chemical operations such as heat transfer and matter transfer Candidates, aged 25 to 35, should possess an honours degree in engineering (preferably mechanical) and have received such practical training as is required for Associate Membership of the major Engineering Institutions Starting salary according to age and experience —Applications giving details of age and experience, should be addressed to the Staff Manager

YOUNG MAN HAVING A NATIONAL certificate or equivalent in physics or electrical engineering is required for a post in the measurement section of a development laboratory in Northamptonshire The work is connected with microwave equipment, but experience in this field is not essential Salary will be in accordance with age, etc —Box 608, T G Scott and Son Ltd 143-147 Regent Street London W 1

BRITISH CHROME AND CHEMICALS LTD require two physical chemistry graduates with research experience, preferably in industry capable of leading small teams with energy and persistence One team to investigate phase relationships in systems at elevated temperatures, the other to deal with problems of a general nature in electrochemistry and surface chemistry and with the development of physico-chemical methods of analysis Salaries will be according to experience and qualifications, and the successful applicants will be eligible for membership of an approved pension scheme after twelve months' service —Applications, which will be regarded as confidential, giving the fullest details of experience and qualifications as concisely as possible should be addressed to W H Morrow, Technical Director, British Chrome and Chemicals Ltd, Urlay Nook Eaglescliffe Stockton-on-Tees

LADY CHEMIST, GRADUATE OR H N C required for analysis of electroplating and allied solutions —Apply Electro-Chemical Engineering Co Ltd 161 Queens Road, Weybridge, Surrey

TECHNICAL DEVELOPMENT

Opportunities exist for Graduates to enter an expanding and interesting field of work Appointments are to be made in both senior and intermediate capacity on the staff of a Development Group engaged on projects entailing a special knowledge of an interest in thermodynamics and physical chemistry Applications are invited from 1 Graduates, with a good science degree and at least four years' research or development experience, and being within the age group 27 to 35 Commencing salary from £1 000 per annum according to experience and ability 2 Graduates with a good science degree and within the age group 21 to 26 Previous experience is not essential, and graduates due to complete their National Service within the next twelve months are also invited to apply Commencing salary from £650 per annum

Applications should be addressed to Box 612, T G Scott and Son, Ltd, 143-147 Regent Street, London, W 1, and give fullest possible information of qualifications and experience

FISONS, LIMITED, REQUIRE TRANSlator proficient in technical German, financial and spoken French Spanish Italian Russian Dutch desirable but not essential Salary according to qualifications Pleasant conditions and pension scheme —Applications to Personnel Officer (L), Fisons, Limited, Harvest House, Felixstowe, Suffolk

DEXION, LIMITED OUR VERY rapid growth and solidly based success is due to a fresh approach to industry We have unusual ideas—one of them is that young men with good scientific or technical background and a thorough understanding of the scientific method could inject new vigour into the organizational and administrative side of industry If you are interested in this idea and feel you have something to contribute, there is scope and opportunity for you in our organization On our part we are prepared to pay well and give all the necessary encouragement, help and training —Write for further details to the Personnel Manager, Dexion Limited 65, Maygrove Road, Kilburn, London, N W 6

PILKINGTON BROTHERS, LIMITED, WHO are the largest manufacturers of plate and sheet glass in the British Commonwealth, and employ more than 20 000 persons, wish to appoint a Head of their Technical Development Department This is a new appointment necessitated by the large number of development projects in hand It is intended that the man selected should take charge of the development of new processes and the radical improvement of existing ones There are ample technical resources available, and the Company spends large amounts on development work Applicants must have a good honours degree in engineering, physics or chemistry They must also have a flair for development work, and the enthusiasm to see a job through Applications will be welcomed from men aged preferably 35 to 45, who have done at least five years' development work in industry or at a university The Company is prepared to offer a service agreement on an attractive salary to the right man The Company operates contributory superannuation and widows pension funds —All applications will be treated confidentially, and should be addressed to the Chief Personnel Officer, Pilkington Brothers, Limited, The Glass Works, St Helens, Lancashire

BOOTS PURE DRUG CO, LTD, REQUIRE a woman graduate in their Microbiology Division to carry out routine assays and investigations into assay techniques on antibiotics and vitamins Experience in this field of microbiology would be an advantage and salary will be according to experience and qualifications —Applications to the Personnel Manager, Station Street Nottingham

ASSISTANT WORKS CHEMIST, PREFERably a graduate with some experience, aged 25 to 30 for development and control of organic chemical processes Capable of working on own initiative with a minimum of supervision —Apply with full details of training and experience and salary required to Box 604, T G Scott and Son, Ltd, 143-147 Regent Street, London, W 1

WOOL INDUSTRIES RESEAR ASSOCIATION

Physicists with honours degree require (1) Fundamental research on adhesion, f and abrasion (2) Weaving research Th involves experimental and analytical investi on looms and in the laboratory, it r mechanical aptitude and a liking for c physics Age 22 to 26 Previous research ence not essential Commencing salary ac to age and experience in range £530 to £8 annum for post (1), and £530 to £665 per for post (2), F S S U benefits

Applications to Wool Industries R Association, Torridon Headingley, Leeds,

THE ENGLISH ELECTRIC COMPAN vites applications for progressive posts Mathematical Physics Group of the Weapons Division, Luton The work co theoretical analysis relating to a wide ra engineering problems and the application tronic analogue and digital computers t solution Applicants should hold at le honours degree in mathematics, physics gineering, and should preferably have had years' experience in engineering research salary will be in accordance with qualifi and experience Assistance with hous commodation may be given —Applicati Dept C P S, 336-7 Strand, W C 2, quotin S A 50B

SMITHS AIRCRAFT INSTRUMENTS have vacancies in their Engine Controls I ment for Senior and Junior Graduate En and Physicists interested in research and d ment of automatic controls for aero gas tu Experience in, and knowledge of theoretica or practical aspects of servo mechanisms, o netic amplifier and electronic technique electro-mechanical equipment, together w appreciation of the requirements for a equipment, would be an advantage would be commensurate with qualification experience —Apply giving details and qu tions, quoting Reference 49/EN to The P nel Department Smiths Aircraft Instruments Bishop's Cleeve, near Cheltenham Glos

BACTERIOLOGIST, WITH UNIVER degree, wanted to take charge of laborator ducing veterinary sera and vaccines M experienced in laboratory techniques and had at least two years' practical expe Knowledge of veterinary work an advantag not essential —Box 619, T G Scott and Ltd 143-147 Regent Street London W 1

TEXTILE CAREERS BRITISH N Spinners, Limited, have several vacanci young graduates who will be given extensiv nological training, enabling them to b specialists in this expanding organization ideal qualification is a university degree i sics, engineering or textiles, and candidates have a natural bias towards applied work selected candidates will be put to work the supervision of experts and training w clude a thorough grounding in the manufa of yarns and fibres, and later in their d ment and processing to meet changing requirements Upon successful complet this training it is intended to employ these ates in responsible positions on either te development and experimental work or field of technical service There will a openings on the commercial side of the bu in which specialized knowledge can be appl the development of new end-uses for the pany's products A realistic salary will b during training, and these vacancies offer tional opportunities to men who are will work hard with a specific object and in a of technical stimulation and progress — should contain full details of academic a ments and a frank statement of ambitions a clinations, these should be addressed Personnel Manager British Nylon Sp Limited Pontypool, and will be treated wit confidence Candidates invited for intervie be given a very clear impression of all implied by this new type of career

LABORATORY ASSISTANT REQU for interesting and varied work in small de ment unit Experience not essential —Wr telephone Sucal Ltd, 1-3 Marban Place, Ladbroke 4774

GRADUATE CHEMIST METALLUR or Chemical Engineer required to deal with lems relating to the installation of electro plant and process control Applicants mus completed military service and be willing to —Apply Electro-Chemical Engineering Co, 161 Queens Road, Weybridge, Surrey

An old firm...Wood Brothers makes a new glass... Firmasil

FIRMASIL low expansion borosilicate glass-ware meets the exacting conditions of the modern laboratory; it is unaffected by acids (except hydrofluoric) and, for practical purposes, by alkalis; it will withstand rapid heating and cooling without breaking; it can be 'lampworked' easily and does not normally devitrify. A brochure describing the chemical and physical characteristics of FIRMASIL and listing the range available will gladly be sent on request.

FLUORITE OBJECTIVES

×50 (1/7 in.) Oil immersion N.A. 0.95
×100 (1/12 in.) Oil immersion N.A. 1.30

These new computations of outstanding merit are designed to be used with the NON-DRYING OIL supplied by us.

Compensating eyepieces ×6 and ×8 are available and should be employed to exploit fully the capabilities of these fine lenses.

Each objective is tested on the BAKER OBJECTIVE-TESTING INTERFEROMETER and only the finest selected material is used in manufacture.

Further particulars on request

THE **Newton**

LONG WORKING DISTANCE ATTACHMENT

. . . provides a working distance of 12.8 mm. between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm. objective.

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

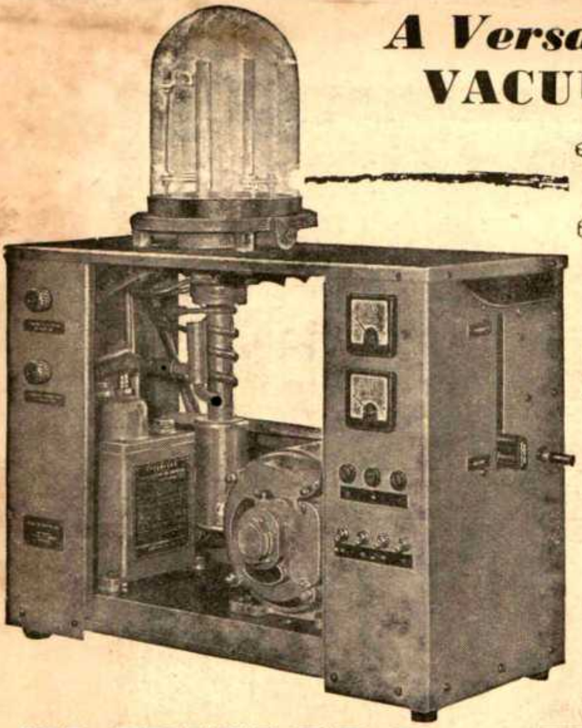
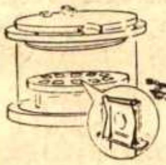
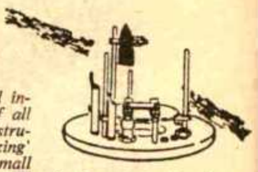
A Versatile Research Tool for VACUUM 'METALLIZING'





Evaporation or sputtering of H.F. quartz crystals with frequency control.

Anti-reflection and interference films of all types for optical instruments. 'Metallizing' plastic mouldings, small mirrors, etc.



Shadow-casting for electron and visual microscopy. Preparing thin films for electron diffraction investigation.

If you require to deposit thin metallic films for experimental, decorative or functional purposes, or wish to try out new production ideas, solve production snags and problems under the same working conditions as the industrial plant, this miniature pre-production research unit is the perfect answer—it REALLY is an extremely versatile high vacuum tool.

The **SCALAMP** *Range*

GALVANOMETERS · FLUXMETERS · ELECTROSTATIC VOLTMETERS

The illustration above shows the operator 'balancing the coil' of a "SCALAMP" GALVANOMETER — one of the final operations in its construction. This instrument, available in a range of sensitivities and incorporating a built-in four-position shunt, is one of the most versatile instruments of its kind. Housed in a robust dust-proof plastic case, it can be operated from mains or battery supply. Two new features, namely a slow-motion drive to the zero control, and an automatic self-shorting foot have recently been incorporated. The truly functional design of the case with built-in lamphouse, transformer and scale renders it adaptable to other instrument types. A FLUXMETER of exceptional performance and a series of ELECTROSTATIC VOLTMETERS (ranges 1-5, 3-10 and 5-18 kV) have already been introduced and a MEGOHM-PER-VOLT VOLTMETER is under development.
Details of the "SCALAMP" range will gladly be sent on request.

Pioneering for Oil

TO THE OILMEN of today goes the credit, and the adventure, of opening up many of the waste places of the earth. Under deserts, prairies, marshes and seas, otherwise bleak and unharvested, may lie oil. Oil for lamps, for cooking stoves, for industry, for farming, for the world on wheels, the ships and aircraft of all nations. The oilmen must always go out and find new sources of supply, so great is the demand. They must drill the wasteland to dredge up the liquid treasure that the earth holds imprisoned.

But that treasure has to be located first. More than a million wells have been drilled for oil through the earth's surface during the last ninety years. But only a fraction of these exploratory drillings have found oil.

Shell Research is constantly advancing the science of oil-finding. Today the aeroplane, the helicopter and the seismograph (measuring waves from man-made earthquakes) help the geologist, the geophysicist, the mineralogist and the palaeontologist.

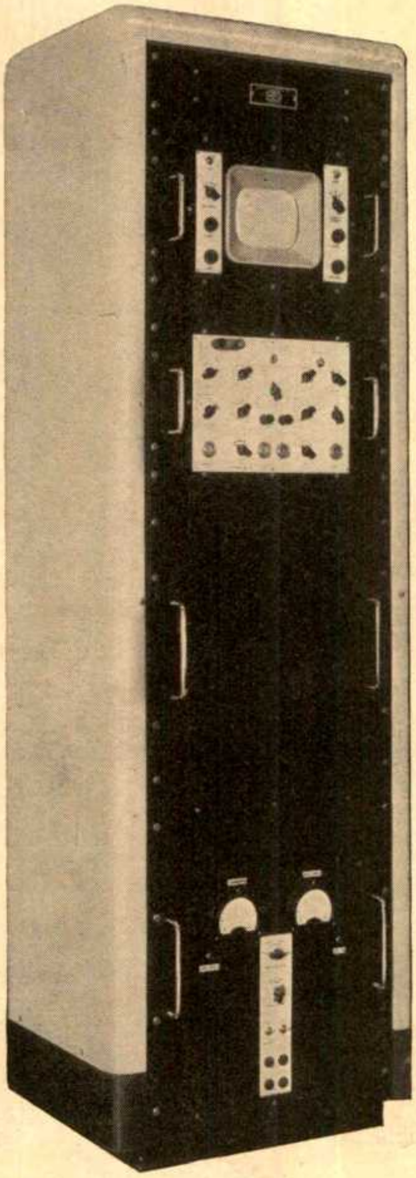
The search for oil is still an adventure, still an advance into the unknown. The oilmen are like the migrating cranes in Homer, settling ever onwards.

SHELL research backs the pioneers

THE SHELL PETROLEUM COMPANY LIMITED, ST. HELEN'S COURT, LONDON, E.C.3.

PROGRESS IN CONTROL

SUNVIC
PULSE HEIGHT
ANALYSER



An instrument for the analysis of a complex pulse amplitude spectrum into groups of known height according to their voltage amplitude.

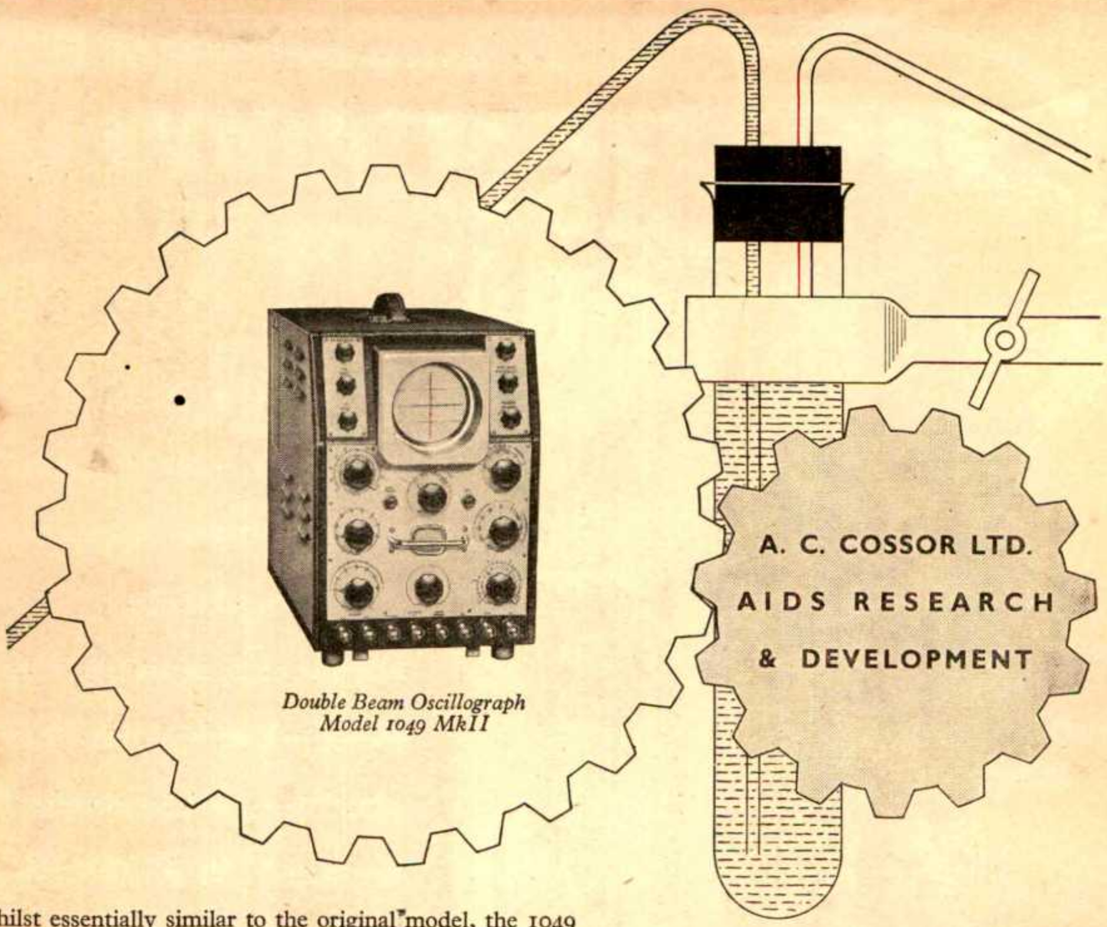
It displays up to a maximum of 120 channels and can store 1,200 binary digits. The design is based on that of Hutchinson & Scarrott (*Phil. Mag.*, 42, 792, 1951) and the instrument is made under licence from the N.R.D.C.

EQUIPMENT BY SUNVIC

SUNVIC CONTROLS LTD. (Special Products Division), No. 1 Factory, Eastern Industrial Estate, Harlow, Essex. Telephone: Harlow 24231/5

Manufacturers of Pneumatic and Electrical Instruments for detection, measurement, control and recording of Temperature, Flow, Liquid Level, Specific Gravity and Pressure, in Science and Industry. Vacuum Pumping and Measuring Equipment, etc.
Member of the A.E.I. Group of Companies.

TAS/Sc.305



*Double Beam Oscillograph
Model 1049 MkII*

Whilst essentially similar to the original model, the 1049 Mk. II provides added reliability against high voltage breakdown by the use of a sealed, oil-filled E.H.T. power transformer. The instrument meets the requirements of Industry and the Research fields of Physics and Medicine by providing an oscillograph for the display and measurement of phenomena of zero or very low frequency and those where amplifier bandwidths of up to 100 Kc/s are required. The oscillograph incorporates the Cossor 4″ flat-screen Double Beam tube (type 89) operating at 2 Kv but provision is made for operation at 4 Kv when maximum spot brightness is required. The amplifier circuits are direct-coupled throughout and provide independent amplifying channels for the Y1 and Y2 Beams with a gain of 900 and 25 respectively from zero frequency to 100 Kc/s. Input signal voltages and frequency may be measured on either channel using the calibrated dials and special anti-parallax graticule. The direct-coupled Time Base is arranged to provide a repetitive or triggered scan with a time range of 1.5 seconds to 150 micro-seconds and can be synchronized from a pulse derived either from the internal work circuits or from an external source. A continuously variable control adjusts the amplitude of the sync. or trigger signal and selects the polarity of the pulse from which synchronization is desired. "Z" modulation system is incorporated for time-marking purposes. Stabilization against mains variations up to 10% is provided for amplifiers and cathode ray tube supplies. Long period stability is reached within 5-10 minutes of switching on. A pre-amplifier (Model 1434) and photographic recording equipment is available for this oscillograph.

The Technical Advisory Staff of the Cossor Instrument Division is always at your service.

C.I.62

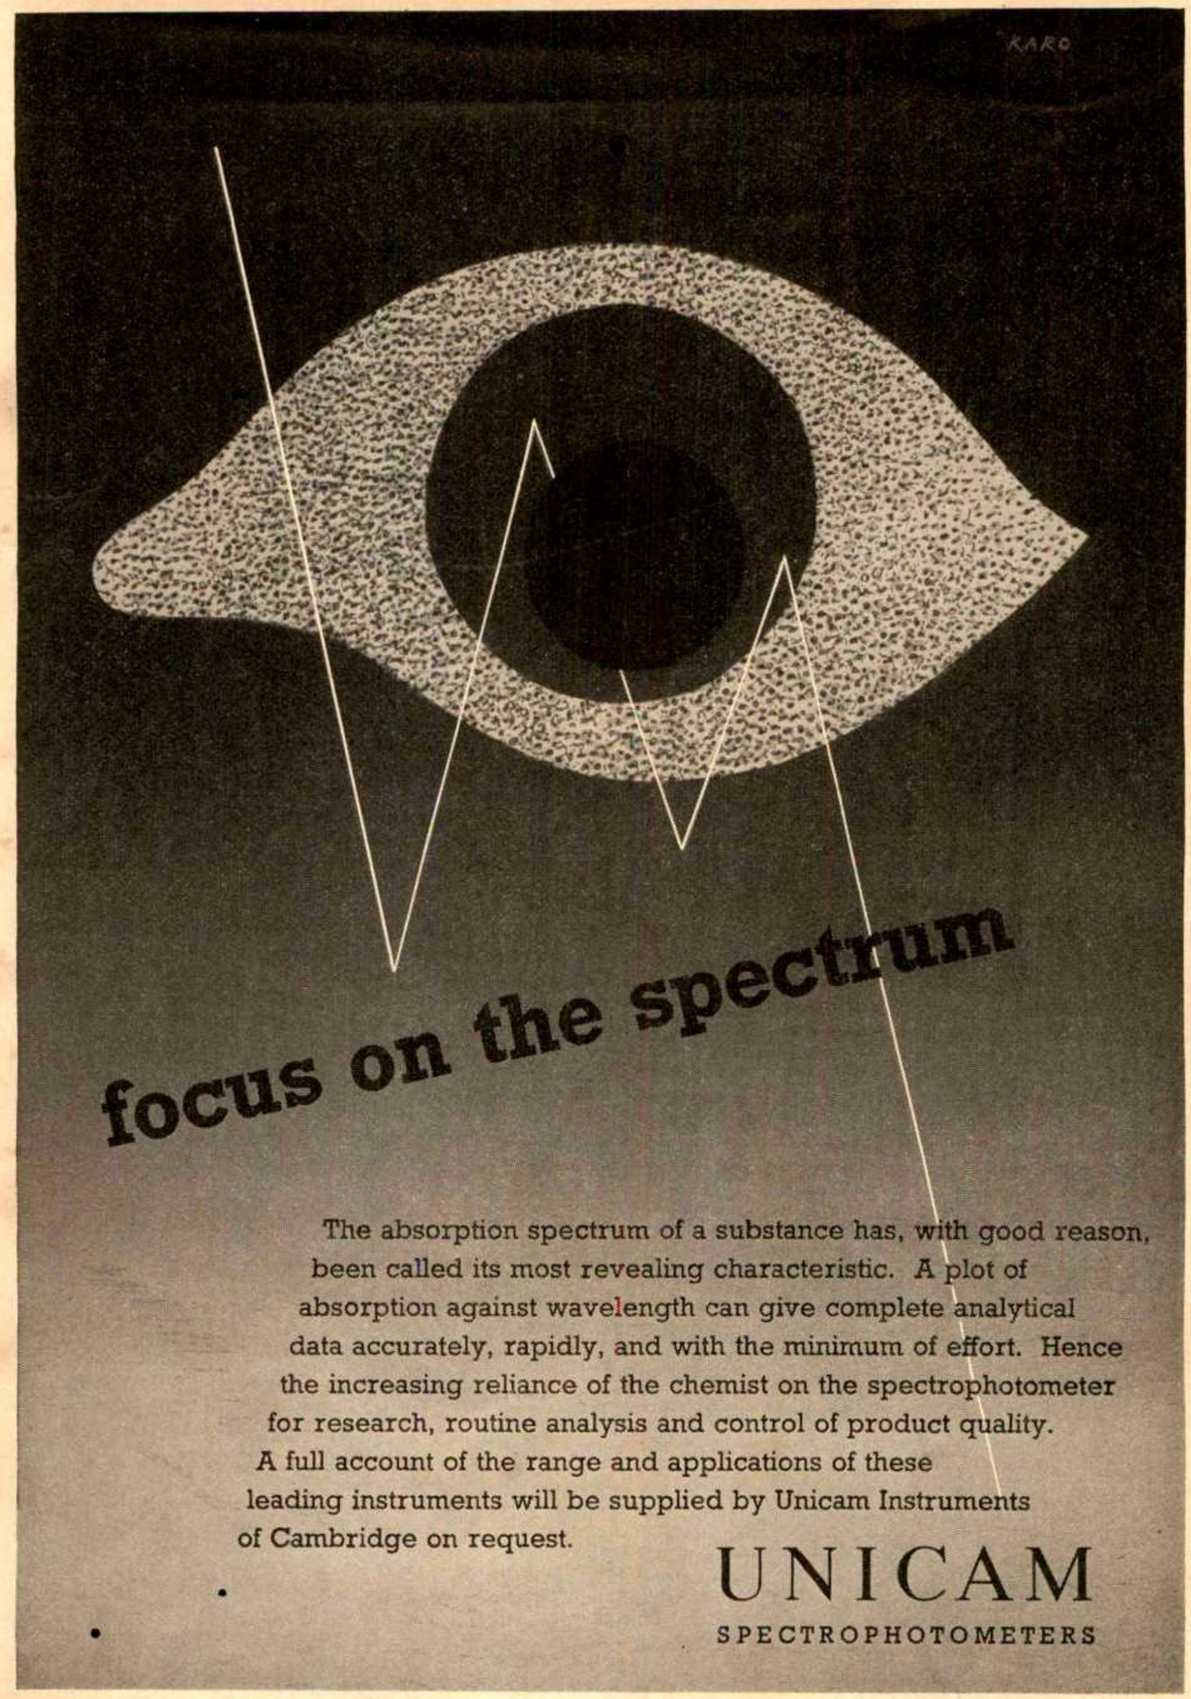
Wherever you need distilled water — in laboratory, factory or shop — you can use 'Deminrolit Water' with equal results. The Portable 'Deminrolit' plant operates by ion exchange and delivers water substantially free from dissolved solids. Running costs are measured in pence instead of in pounds, and you can thus use distilled quality water for many purposes where the cost of distillation would prove prohibitive.
Please write for Technical Publication No. 62 which gives full details.

HIRE SERVICE

Why not try demineralised water in your industry? You can do so easily and cheaply by hiring from us, at a nominal rental for a trial period, the latest Mark II Model Portable 'Deminrolit' Plant. Details of this service will gladly be supplied on request.

PERMUTIT 'DEMINROLIT'

THE PERMUTIT COMPANY LIMITED
(Dept. V.H. 173), Permutit House, Gunnersbury Avenue, London, W.4. *Telephone : CHIswick 6431*



The absorption spectrum of a substance has, with good reason, been called its most revealing characteristic. A plot of absorption against wavelength can give complete analytical data accurately, rapidly, and with the minimum of effort. Hence the increasing reliance of the chemist on the spectrophotometer for research, routine analysis and control of product quality. A full account of the range and applications of these leading instruments will be supplied by Unicam Instruments of Cambridge on request.

SUPPLY OF SCIENCE TEACHERS IN BRITAIN

ATTENTION has been focused on the continuing shortage of science teachers in Britain by the reports of the Federation of British Industries and of the Advisory Council on Scientific Policy, by a resolution at the annual meeting of the Trades Union Congress and by a discussion at the Conference of the Universities of Great Britain and Northern Ireland held in London during December 17 and 18. Naturally, the subject has also been discussed during the recent meetings of educational bodies The term 'science teachers' refers to teachers of science or mathematics in public schools, grammar schools or other schools with a significant number of sixth-form pupils It is now accepted that there is a shortage of science teachers, that their quality is lower than it was before the War, and that the shortage is a matter of national concern because it threatens the supply of science students to the universities and so the supply of scientists to industry—and hence the standard of life of the whole community It is also clear that the shortage will continue for some decades, unless prompt measures are taken, because of the growing demand of industry and the Scientific Civil Service for more scientists and technologists

The situation demands two things first, prompt measures to alleviate the present situation , secondly, an analysis of the fundamental causes of the shortage and the reluctance so far shown to take steps to end it, so that long-term remedies can be applied to secure for the schools a full supply of science teachers of good quality, which must be done before the greatly increased supply of scientists needed by the community will be forthcoming The reports of both the Advisory Council on Scientific Policy and the Federation of British Industries rightly stress that the only permanent solution for the shortage of science teachers is the production of more science graduates , but they fail to emphasize that more science graduates cannot be produced until the shortage of science teachers has been made good

A number of minor suggestions for immediate action to alleviate the present shortage were made in the report of the Federation of British Industries, and also by speakers at the Universities Conference Many of them have been common practice for the past five years in schools—at best they are merely palliatives They cannot of themselves reverse the trend which has set up the present deflationary spiral of fewer science teachers leading to fewer science graduates, producing still fewer science teachers and so on But there are two immediate steps which, if taken, might materially reduce the present shortage of science teachers—they might even reverse the deflationary spiral. Scientists are in short supply , during the Second World War, articles in short supply were rationed Something similar might now be attempted for scientists A high-level conference of the interests using scientists—the Scientific Civil Service, industry, the universities and the schools—should be called to try to secure a fairer distribution of scientists Direction of labour is clearly out of the question , but, when industry and the Scientific Civil Service know the facts, they might be ready to help themselves in the long run by decreasing their demands for scientists for a time, and so help the schools to get more science teachers now This suggestion was the leading recommendation of the report issued in November 1953 of the National Advisory Council for the Supply and Training of Teachers , but no action was taken The Minister of Education ought to have taken the initiative, and that no such conference has taken place suggests lack of courage and faith in the grammar schools, it is the task of the present Minister to convince his colleagues in the Government that the grammar schools hold the key to the solution of the problem of the shortage of scientists The Advisory Council on Scientific Policy would then be a suitable body to which this fairer distribution of scientists could be immediately referred

An apt analogy was recently given by Dr. A W Barton, headmaster of the City of London School After the War, Britain was short of coal, its most precious and most abundant raw material, because there were not enough miners , so coal mining was made a form of national service, and this has had some effect in attracting more men to the mines and increasing production We are now short of a precious human commodity, science teachers , therefore, the possibility of recognizing teaching as a form of national service should be considered This would increase the number of science teachers coming into the schools in the year it was introduced from six hundred to nine hundred, because men teachers coming into the schools at the end of their national service would be joined by an equal number who had just graduated and would just have been starting national service in the Armed Forces It might also do something towards a permanent solution of the problem by attracting some new men into teaching, some of whom would like it and would stay on The compromise on national service proposed in the report of the Federation of British Industries is satisfactory neither to the Armed Forces nor to the schools The Armed Forces can make no use of men who are to have only the six months or so needed to complete their basic training The compromise is unfair to the schools because it fails to do justice to the serious shortage of science teachers and their present importance to the country

The fundamental cause of the present shortage of scientists in general and science teachers in particular is the policy of full employment and the great increase in the demand for scientists since the War Two other factors in the shortage of science teachers in particular are the exaggeration of the importance and satisfaction of research, and the decline in the prestige and financial rewards of science teaching. The steps needed to reverse the deflationary spiral and abolish the shortage of scientists would therefore seem to be fairly clear The pre-war economic pressure due to unemployment, which provided that a sufficient number of science graduates should be available for teaching, disappeared when Britain adopted a policy of full employment, and science graduates must now be induced to go into teaching by pointing out to them the importance of the work and by suggesting to them that it is the duty of those with the right qualities to take up teaching Much might be done to this effect by arranging an annual visit to the pure science departments of each university by a headmaster or assistant master, during which third-year undergraduates and research students could be told by practising schoolmasters about the responsibilities, opportunities and rewards (financial and spiritual) of science teaching, such talks would also have to make clear the importance of science teaching in the national life The staffs of the universities could perhaps do more, through their considerable influence with undergraduates, to persuade them to consider teaching as a career, the help of the university appointments boards and the Youth Employment Service should also be sought

The schools themselves can help in a number of ways Headmasters should take care, so far as their authority permits, to give their staffs good working conditions inside the schools They could use their influence to try to persuade more pupils to stay on in the sixth form, they could stress the urgent national need for scientists when advising pupils on their choice of sixth-form studies, they could put the claims of teaching fairly before their pupils when advising them about careers Finally, boys and girls are influenced more by what their teachers are than by what they say If science teachers are keen, competent and devoted to their pupils, that in itself will induce in young people a respect for teaching as a profession and will result in more of them taking it up Local education authorities can help by giving to the grammar and other secondary schools the freedom and prestige which the grammar schools enjoyed before the War and have since lost, and by ensuring that science teachers are not passed by when headships are under consideration

There is no question that research attracts many graduates This is due partly to the spectacular achievements in recent years both of the physical and the biological sciences, which have led graduates to believe that this is the chief road to fame But they have often heard only about the successes, they fail to realize that these results often involve thousands of graduates and technicians, and they do not appreciate that research, like teaching and any job which is worth while, has its monotony, its failures, and perhaps more than its fair share of bewilderment and frustration. Some of the responsibility for the powerful attraction of research, however, is due to failure to maintain a proper balance in the universities between their two functions, teaching and research It has been suggested that too many of the teaching posts in universities are filled by men interested primarily in research The universities should re-examine the relative importance of teaching and research, of transmitting accepted truth to the next generation and of finding new truth If they fail in the first function, must not the second of necessity wither away ? When the universities have ensured that there is in each science department on man, of the status of a reader or occasionally a pro fessor, who holds his important post because he is distinguished teacher of his subject, then a highe proportion of undergraduates is likely to take u science teaching

We shall only get enough science teachers in thi age of full employment if we set out to produce youn men and women with the right qualities, namely, a interest in science and an equally great interest i persons One step which the universities could tak to produce young men and women likely to mak good science teachers would be to devise genera honours degree courses in which arts and scienc subjects could be combined While there is n evidence that there is undue specialization in scienc in the schools (indeed, in most schools all pupil spend two-thirds of their time on the humanitie until they reach the sixth form and begin t specialize), they must also help in this respect b providing stimulating courses in the humanities fo their science specialists, and using their influence t see that their pupils take this part of their curriculum seriously

Finally, headmasters in schools and professors i universities cannot in honesty tell their pupils how important science teaching is and appeal to the sense of duty of those suitably qualified to take it up, unless they can also assure them of reasonable financial reward Before the War, a science teache had the same salary as a university lecturer, and a senior science master the same as a reader or senio lecturer To-day the university lecturer rises to £1,350, whereas a science teacher rises to £950 unde a generous local authority, the senior lecturer rises to £1,600, while a senior science master rises to £1,200 with a very generous local authority or to £950 under a niggardly one The science teacher is clearly underpaid to-day When the Education Act was passed in 1944, it was decided that all children were to have a proper secondary education, which implies that all secondary schools should have classes of reasonable size, buildings with comparable amenities and teachers paid on a common salary scale This has meant that the salaries of the teachers in all types of school—primary, secondary modern and secondary grammar—are settled by a Burnham Committee in which grammar school teachers are very much in a minority This has produced the expected effect on the salaries of teachers, the pay of the average worker has been increased at the expense of the fewer highly skilled workers, and the highly skilled minority feels that it is being unjustly treated The Burnham Committee has been trying to work out a suitable salary scale for all teachers in the State schools for ten years, it has failed to do justice to the teachers in the grammar schools, which, from the point of view of progress and development, are the most important schools to the community, and it is clear that the Burnham Committee as at present constituted is very unlikely to solve this problem The Minister of Education has just asked them to decide if the salaries now being paid to grammar school staffs are good enough to attract distinguished teachers Unless the Minister's lead induces the Burnham Committee to award a substantial increase in grammar school salaries, a Royal Commission to consider the salaries of teachers in grammar schools and the problem of their recruitment appears to be desirable This question of salary is not the only factor to be considered, but it seems fairly certain that the present shortage of science teachers is unlikely to be overcome until more attractive salaries are offered.

LECTURES BY SIR HENRY DALE

An Autumn Gleaning

Occasional Lectures and Addresses By Sir Henry H Dale Pp x+225 (London Pergamon Press, Ltd , 1954) 21*s* net

IN 1953 the Pergamon Press published a collection of famous original papers by Sir Henry Dale under the title "Adventures in Physiology" (see *Nature*, 172, 825 , 1953) The same publishers have now persuaded Sir Henry to prepare a smaller book with a more general appeal containing thirteen lectures and addresses mostly delivered during the past ten years, and extracts from five war-time presidential addresses to the Royal Society

This book contains a mixed bag of good reading-matter written with easy and explicit fluency, and intelligible without specialized knowledge There is an account of the history of work on viruses up to 1935 The discovery of insulin is described with the authority of one who was in direct contact with the original work and yet able to be impartial The case for the freedom of science and the case for the inclusion of some knowledge of science as an essential part of a liberal education are put with convincing clarity and force There are two addresses to young men on "Experiment in Medicine" and on "Medical Research as an Aim in Life" The popular lecture on "Accident and Opportunism in Medical Research", delivered in Cambridge at the annual meeting of the British Medical Association in 1948, is particularly valuable since it contains interesting details, not given in the original publications, of how great discoveries have been made It is good to see in print the stories of the discovery of Ringer's solution through the laziness of a technician and of Dr Oliver's injections of adrenal extracts in his son

The book also contains addresses in honour of William Whitla, Thomas Addison and Lord Rutherford and the lecture given in connexion with the Festival of Britain reviewing a hundred years of medical progress The last two lectures are up-to-date reviews of a more technical kind dealing with two topics on which the author is the chief authority —the mechanism of anaphylaxis, and the transmission of effects from nerve endings

After an active life spent in leading the advance beyond the frontiers of knowledge in various specialized fields, Sir Henry has had the time between the ages of seventy and eighty years to turn his mind to problems of more general importance He has considered the place of science in the modern world and its effects on mankind , he has important things to say on these matters and the power to say them effectively This book is an anthology of his unmistakable and characteristic English prose and can be recommended to all who are interested in medical and allied scientific research J H GADDUM

FLOW PROPERTIES OF DISPERSE SYSTEMS

Flow Properties of Disperse Systems

Edited by Prof J J Hermans (Deformation and Flow Monographs on the Rheological Behaviour of Natural and Synthetic Products) Pp xi+445+12 plates (Amsterdam North-Holland Publishing Company New York Interscience Publishers, Inc , 1953) 35 florins , 70*s*

THIS volume is one of a series of monographs describing the rheological behaviour of natural and synthetic products The particular disperse systems with which it deals are those containing 'large' particles well beyond ordinary molecular size, but sufficiently small to exhibit, in some instances, marked Brownian motion , it is assumed that the laws of hydrodynamics of continuous fluids are applicable to such systems provided the particles have dimensions of the order of ten times the molecular dimensions of the dispersion medium

The ten chapters into which the book is divided treat of suspensions, emulsions, gels, dilute solutions of impenetrable rigid particles and flexible chain molecules, liquid sprays, atomization of liquids, foams, smoke and powders The field covered is therefore wide and diverse, and the various authors have had to select, from a considerable literature, those aspects which they regard as of particular significance in the development of their subject This limitation results in some lack of balance and some obvious omissions which are, however, in part made good by extensive references to standard works and to original papers

The rheological properties of suspensions, emulsions and gels have many characteristics in common best illustrated by a comparison of their visco-elastic behaviour , and much of the recent work described by R Roscoe, E G Richardson and J J Hermans in the first three chapters is concerned with the viscosity–concentration relationships of typical examples of the three systems The theoretical treatment is usually based upon hypothetical models of the molecules concerned , thus, for example, Kuhn, Wall, Hermans and Treloar have developed a theory of long-chain molecular networks applicable to rubber, and Kratky has used a model consisting of chains of rigid rod-shaped crystalline units joined by hinges and embedded in a continuous plastic medium to interpret the behaviour of cellulose gels In this way, quantitative expressions for force–strain relationships and the volume change on stretching have been derived

In recent years, a great deal of valuable data on the shape and dimensions of macromolecules and the structural characteristics of gels have also been obtained by a study of the flow characteristics of their solutions Ch Sadron and J J Hermans have given an excellent account of the theory of Brownian movement as applied to dilute solutions of impenetrable rigid particles and of the equivalent particle concept which has been used by Flory in the development of a theory of viscosity applicable to dilute solutions of flexible chain molecules

The extensive use of sprays, aerosols and smokes for insecticidal and other purposes has led to further studies of the mechanism of drop formation, distribution of drop-size and rates of dispersion and settlement of aerosols and smokes E G Richardson gives a comprehensive account of the break-up of liquid jets and the methods of measuring drop-size, while H L Green summarizes recent work on the atomization of liquids and the properties of smokes R Matalon describes the rheological properties of foam and the methods available for studying the mechanical properties of the stabilizing surface layer of laminæ and bubbles The concluding chapter by Mrs B S Neumann contains an account of the flow properties of powders

INTERPRETATION OF EARTHQUAKE DATA

Earthquake Intensity and Related Ground Motion
By Frank Neumann Pp v+78+figures 1–16 (Seattle University of Washington Press, 1954.) 1 50 dollars

THE author of this booklet is a noted mathematician and was employed for a prolonged period as chief seismologist at the United States Coast and Geodetic Survey, retiring in August 1953 The booklet surveys part of this work and summarizes our present knowledge of this most important part of seismology, including much original and previously unpublished work by the author It is a publication replete with experience and written with the incisiveness and succinctness of the mathematician

The old way of determining earthquake epicentres by drawing isoseismal lines required the precise formulation of seismic intensities, and in 1931 H O Wood, at the Pasadena Seismological Laboratory, brought up to date the Mercalli–Cancanni intensity scale Now seismic intensity, which is in effect a measure of the local destructiveness of an earthquake, is made up of a great number of factors, chief among which is probably local ground acceleration Nowadays, ground acceleration alone is measured by 'strong-motion' seismographs In 1935, C. F Richter published an earthquake magnitude scale in which the magnitudes of earthquakes are obtained from the measurements of standard seismograms reduced to standard epicentral distances, and are a function of the energy released by the earthquake The most recent formula of B Gutenberg and C F Richter is $\log E = 12 + 1\ 8\ M$, where E is the radiated energy and M the earthquake magnitude. Earthquake magnitude does not refer to local energy near the observatory, but to the total energy released at the focus of the earthquake

Efforts have been made, and are being made, by seismologists throughout the world to define seismic intensity with mathematical precision, obtaining the data from seismograms instead of from human perception and the destruction of buildings, and to relate seismic intensity at any focal or epicentral distance to earthquake magnitude at the focus of the earthquake This is precisely the task Frank Neumann set himself In the present booklet he develops a distance–Modified Mercalli intensity relationship, particularly from the data concerning the Puget Sound earthquake of April 13, 1949 The intensities are the lowest intensities and refer to the basement rock outcrop In all earthquakes the intensity on this formation is reduced approximately one grade whenever the distance is doubled This distance–intensity graph always indicates an epicentral intensity corresponding to the Gutenberg–Richter magnitude at an epicentral distance of about one mile Intensities on highly compacted sedimentary rock outcrop are consistently about one Modified Mercalli grade higher than on granitic outcrop at all epicentral distances A relationship is established between Modified Mercalli intensity and maximum acceleration This relationship varies with epicentral distance With increase of epicentral distance the acceleration for a given Modified Mercalli intensity grade decreases, but the duration increases

Period-acceleration envelopes exhibit the following characteristics At short epicentral distances they show a peak on the average at about 1/3 sec period, but the period of the maximum acceleration waves increases with epicentral distance For the waves of shorter period the rate of increase of acceleration with increase of period is indicative of body-wave propagation and apparently varies greatly with the type of rock traversed and epicentral distance For waves of longer period the rate of decrease of acceleration with increase of period is practically constant and indicative of layer vibrations in, or related to, basement rock formations. The author develops a technique, employing intensity-acceleration relationships, whereby Modified Mercalli intensities are determined from period-acceleration envelopes They consistently agree with the intensities obtained from the author's distance–intensity graphs Further, a quantitative intensity grid developed by the author from the intensity-acceleration and period-acceleration relationships, and valid up to an epicentral distance of approximately twenty-five miles, shows the acceleration or amplitude to expect for any period that may be in the ground motion. Modifications for distances exceeding twenty-five miles are discussed. Grids are developed for period-acceleration distribution when earthquake foci are in the granitic basement, and for period-acceleration distribution when earthquake foci are in the highly compacted sedimentary rock above Grids are used to interpret period-acceleration envelopes, or individual waves, in terms of Modified Mercalli intensity

The author states that "since the intensity distribution on basement rock is always very uniform, so-called basement rock intensity data may be used to determine maximum intensity epicentres These are points of maximum energy release and do not necessarily coincide with epicentres obtained from standard seismograph records, which indicate the location of the first rock break where more than one break occurs The rapid decrease of intensity on basement rock outcrop with increase of distance in the immediate epicentral area indicates that major rock breaks are quite limited in extent The intensity distribution in all shocks thus far studied is the same as though the foci were all very shallow regardless of the actual depths revealed by teleseismic data". A casual comparison of period-acceleration envelopes and earthquake spectra obtained from identical instrumental records reveals a marked similarity in their overall forms Further study, however, is needed to determine to what extent such envelopes may be used as substitutes for earthquake spectra

The use of simplified ground motions in engineering studies as substitutes for actual ground motions poses a difficult problem. While the quantitative intensity grid as developed by the author furnishes period and amplitude data on earthquakes of different Modified Mercalli intensity, the important element of duration s missing, as Neumann admits. He suggests, however, a substitute procedure. He further states that a '22-fold increase in acceleration is indicated" when arthquake vibrations passing through the granitic asement force the most responsive types of surface ormations into vibration. (The United States Bureau f Mines, while investigating high-frequency explosion vaves, found a thirty-fold increase between two xtreme types of rock and soil formation.)

The author is at pains to direct attention to the rovisional character of all the new relationships ut forward in the text, and suggests new types of nstruments, which at low cost would assist the ractical and theoretical investigations brought to ight by this erudite booklet. Engineers concerned vith earthquake-proof design and those concerned vith insurance in countries liable to earthquakes, o less than all seismologists, will read this stimulating vork with interest and profit. ERNEST TILLOTSON

ELEMENTARY APPLIED PSYCHOLOGY

Psychology applied to Human Affairs

By Prof. J. Stanley Gray. Second edition. (McGraw-Hill Series in Psychology.) Pp. vii+581. (London: McGraw-Hill Publishing Company, Ltd., 1954.) 12*s*. 6*d*.

THIS book is designed as a 'class-room text-book' for first-year students in psychology. Its major emphasis is on industrial psychology. The reatment of educational, clinical and medical psychology is very slight. Some of the less orthodox opics it deals with are "Psychology in College Life", 'Military Psychology", "Speech Correction", and 'Psychology in Marketing and Advertising". Social psychology, too, is represented in chapters on "Public Opinion and Propaganda" and "Crime and Crime Detection". Since the book is written at a fairly lementary level, it is to be expected that the changes rom the first edition, published in 1946, are small. The main justification for the new edition seems to e the bringing up to date of descriptions of the ractice of some American institutions that make use of applied psychology.

The editor, who is also author of nine of the nineteen chapters, emphasizes that the book aims at eing "factual and practical", and "theoretical discussion . . . has been kept at a minimum", and hat sometimes, because of limited space, "facts are eported with a minimum of interpretation". Hence 'it needs a teacher to interpret the facts", though he editor suggests that by using this as a classroom ext-book the teacher can dispense with formal ectures. This may excuse what sometimes appears nconsequent and arbitrary. But the approach could e more scrupulous. Too often results of dubious alue are quoted without tests of significance or, in ome cases, indication of the number of cases upon which the results are based. The writers take the eader too little into their confidence about the roblems and difficulties facing the applied psychologist, and the presentation by topic leads to a neglect f questions of method. The interview, for example, s basic to a number of topics dealt with in this book; ut no writer has the space to give it the systematic reatment it deserves. Some good features of this ook—statistics showing the need for applied psychology in various fields, descriptions of the institutions that carry it out—are of less value to readers in Great Britain since they refer almost entirely to America. In particular, the very cursory chapters on clinical and military psychology are robbed of their value by this practice.

The standard of text-books in psychology is perhaps a modest one, and by such a criterion this book may not be much below average. But it may be questioned whether its loose, episodic structure makes it a satisfactory compendium of subjects that more specialized text-books in particular fields of applied psychology already cover adequately in university courses. W. H. N. HOTOPF

BIRD PHYSIOLOGY

Avian Physiology

By Prof. Paul D. Sturkie. Pp. xii+424. (London: Baillière, Tindall and Cox, Ltd., 1954.) 48*s*.

ONE might cavil at the use of the above title for a volume that deals essentially with the physiology of the domestic fowl, duck and pigeon. But when we reflect that 90 per cent or more of "text-books of physiology" are in fact text-books of rodent, rabbit and human physiology, any criticism of the title chosen by Prof. Paul D. Sturkie would be a little unfair. The present book is, in fact, probably the first in any language devoted solely to the physiology of birds.

The book deals comprehensively (five chapters) with what is known of avian blood and its circulation, including a chapter on electrocardiography. Three chapters give information on those enormously interesting subjects, avian respiration and the regulation of body temperature. Another one is devoted to energy metabolism, including a statement of what is known (and what is not known) concerning the mechanism that governs moult. Mechanical and chemical aspects of alimentation are dealt with, and there is a chapter on carbohydrate metabolism.

There are also chapters on renal physiology, the special senses (but not the nervous system) and reproduction, together with an account of early embryonic development. The final five of the twenty-one chapters deal with the endocrine glands and their relationships.

This book may become indispensable to the numerous workers in what has become known as poultry science in the United States and elsewhere. It could be valuable, to a limited degree, to the ornithologist who has sufficient physiological grounding to understand it.

The principal criticism that must be made is that, written chiefly for research workers in a very specialized economic field, the book ignores great bodies of available knowledge that vitally need to be written into a single volume. There is nothing about digestion in fish- and flesh-eaters, or the mechanics of, or the remarkable adaptations towards, locomotion. The highly suggestive work of Wood Jones on olfaction in the Turbinares has been ignored and there is little about the neuro-endocrinal control of display, breeding seasons and migration. Perhaps we may hope for a later expansion of the volume to make it truly a text-book of avian physiology. There can be few people better equipped to do this than Prof. Sturkie. A. J. MARSHALL

PRODUCTION OF ENRICHED NON-RADIOACTIVE ISOTOPES AT OAK RIDGE NATIONAL LABORATORY

By DR. C. P. KEIM
Oak Ridge National Laboratory, Oak Ridge, Tennessee

THE production-scale mass spectrographs at Oak Ridge, originally developed to enrich uranium-235, now provide more than two hundred different enriched isotopes of nearly fifty elements for basic and applied research.

Only four of the large mass spectrographs are in active operation for general isotope separation. These were originally installed to provide training facilities for production personnel and to develop ion sources and isotope collectors to be used in large-scale enrichment of uranium-235. These four mass spectrographs, arranged as pairs in two separate magnetic fields, have proved to be highly versatile in enriching naturally occurring isotopes of many elements from lithium to uranium in mass. Radioactive isotopes, artificially produced, have also been separated to a limited extent.

The Production Mass Spectrographs

These Oak Ridge electromagnetic isotope separators (sometimes referred to as calutrons, since the production models were developed at the Universit of California, under Prof. E. O. Lawrence) consist o an ion source and an assembly of isotope collecto pockets mounted in a vacuum chamber between th poles of a powerful electromagnet. The gap betwee the poles of the magnet is 12 in. in one case an 24 in. in the other; the magnetic field may b regulated at whatever strength is desired, up to a least 10,000 gauss. The operating vacuum is in th vicinity of 10^{-5} mm. of mercury. Fig. 1 shows th front view of a calutron and Fig. 2 is a photograp of a model of the magnet, the bins and the vacuu pumps.

A suitable charge material of the element, th isotopes of which are to be separated, is vaporize and fed into the graphite ionization chamber. Electrons of a few hundred volts energy from a tungste or tantalum filament are directed through a collimating slot into the ionization chamber, wher collisions with the gaseous charge material result in a high number of positive ions. These ions are the accelerated from the ion source by means of a

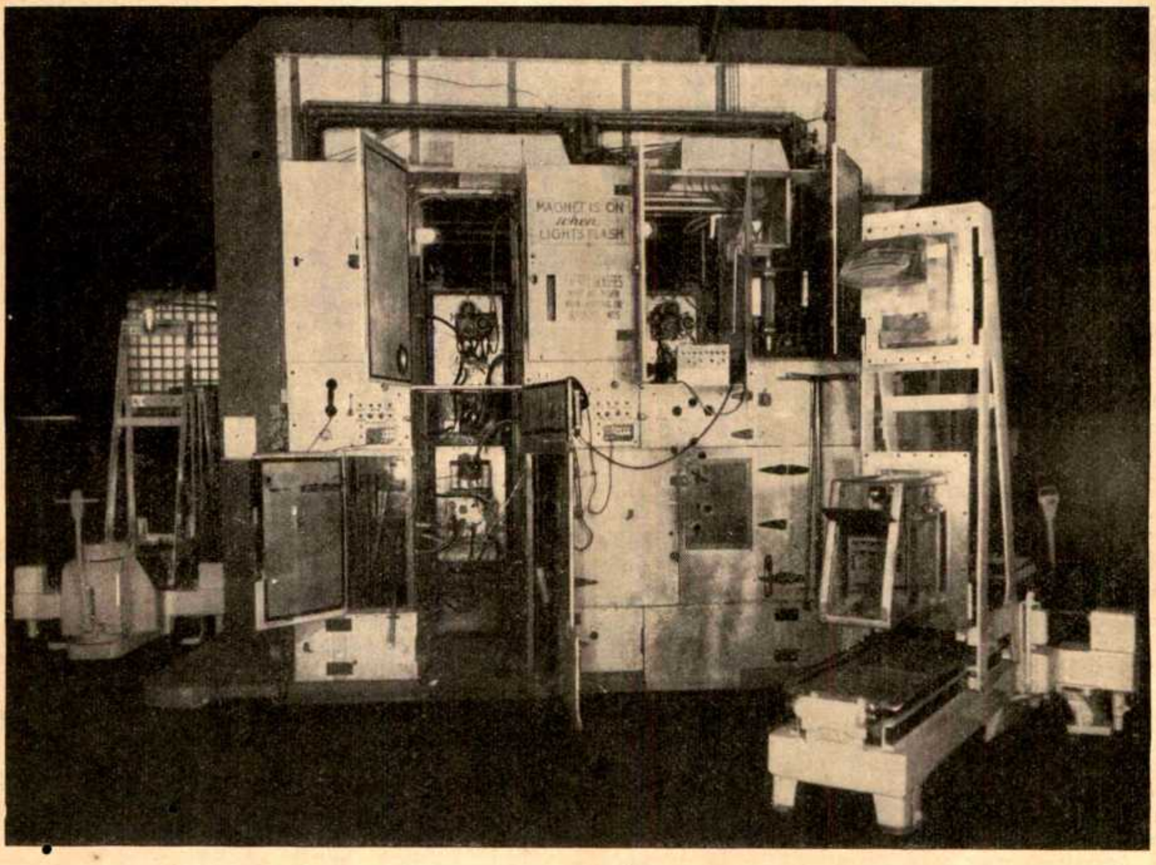

Fig. 1. Front view of the calutron assembly showing the magnet yoke, mass spectrograph spaces, and a handling truck on which are mounted an ion source (below) and the isotope collector (above). The left bin doors are open showing the ion source (below) in its port with all electric and water connexions made and the isotope collector (above) ready for operation. The right bin has the lower doors closed to protect personnel from high voltage during operation

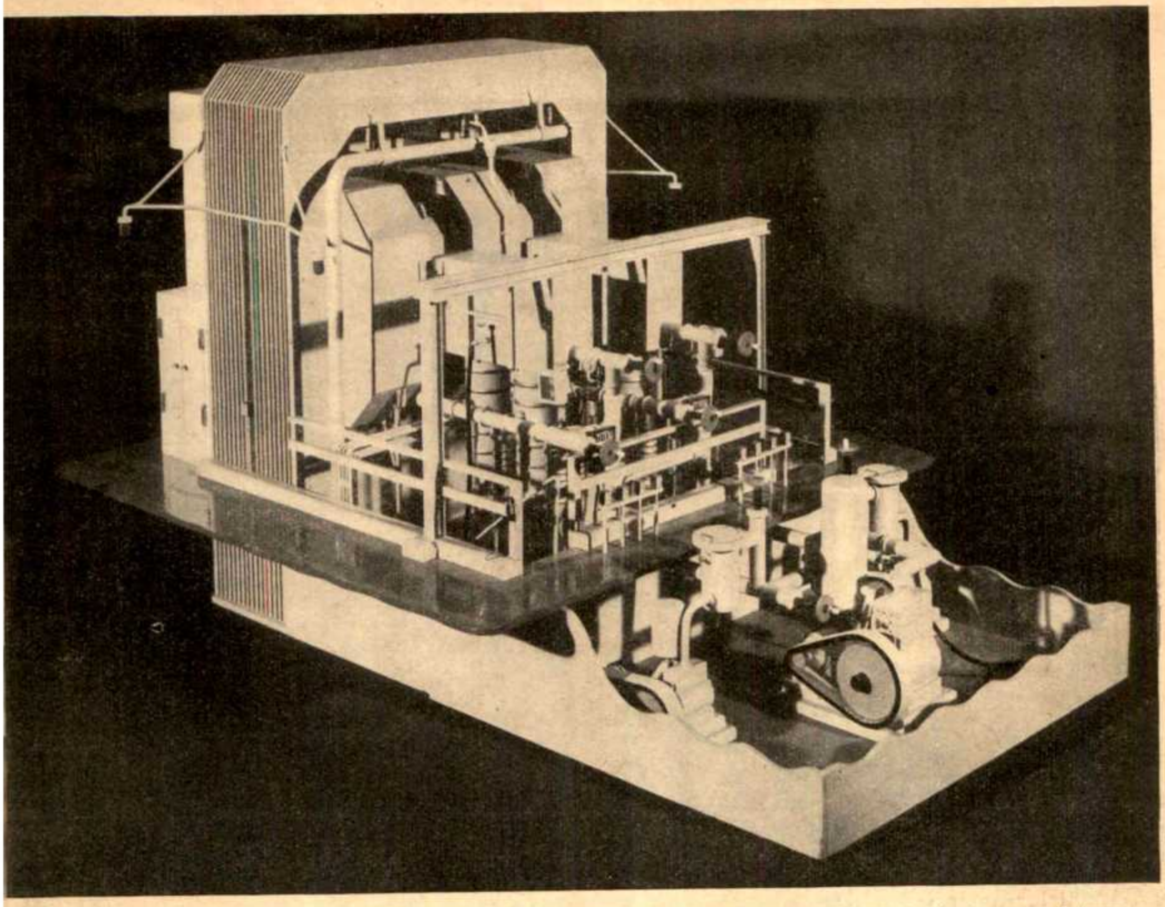

Fig. 2. Rear view of a model of the calutron assembly showing the magnet yoke, three vertical magnet coils, two spaces between the pole-faces of the magnet each for a mass spectrograph, vacuum pumps, valves and piping systems. The mechanical vacuum pumps are on a floor below the main operating level

ectric field of 35 kV. As the ions travel across the agnetic lines of force they are further accelerated to a circular path ; the radius of travel can be aried from 6 in. up to 48 in.

At the 180° position the ions, now separated ccording to mass, are directed into isotope collectors t ground potential. Usually the isotopic material is tained in these collectors in its elemental state.

It has been found that the singly charged ions of e element are the most plentiful. Fig. 3 indicates e variety of ions emerging from the ion source uring typical operations.

Observations drawn from Processing Experience

Various observations have been made in the proessing of nearly a thousand lots of separated isotopes f many elements since early 1946.

The halides have usually proved to be the best harge materials, although oxides and the element self are sometimes preferred. Ion-source oven mperatures may be successfully operated at temeratures as low as 100° C. up to more than 2,500° C. ne or more ionization arcs may be mounted on one n-source assembly, with corresponding increase in roductivity, if there is not too much overlapping of e isotopes at the collector pockets.

Failure of the tantalum or tungsten filaments hich supply electrons for ionization is the most ommon cause of interruption of isotope separation runs. This failure is due to positive ion bombardment and chemical attack.

The percentage of material vaporized from the charge bottle actually getting to the isotope collectors varies widely, from only a few per cent up to as high as fifty per cent, depending on the element being processed.

Graphite collectors are preferable if the collected isotopes have a low vapour pressure and the collector pockets do not require water-cooling. Water-cooled copper collectors have proved best for isotopes of high vapour pressure to prevent high loss of the collected isotopes. Under adequate control, almost one hundred per cent of the material reaching the collector pockets can be successfully retained there.

Every element has its characteristic chemical and physical properties, and the performance of an element cannot be successfully predicted on the basis of the behaviour of similar elements.

Key Steps in Isotope Separation

The key steps in successful isotope separation require various technical skills. Inorganic chemists must aid in the selection of suitable charge materials of the elements to be processed, including rare and unusual materials, then prepare adequate quantities of the chosen forms in high chemical purity. They must recover small quantities of the precious enriched isotopes from the collectors, purify them chemically, and supply them in a variety of chemical forms for

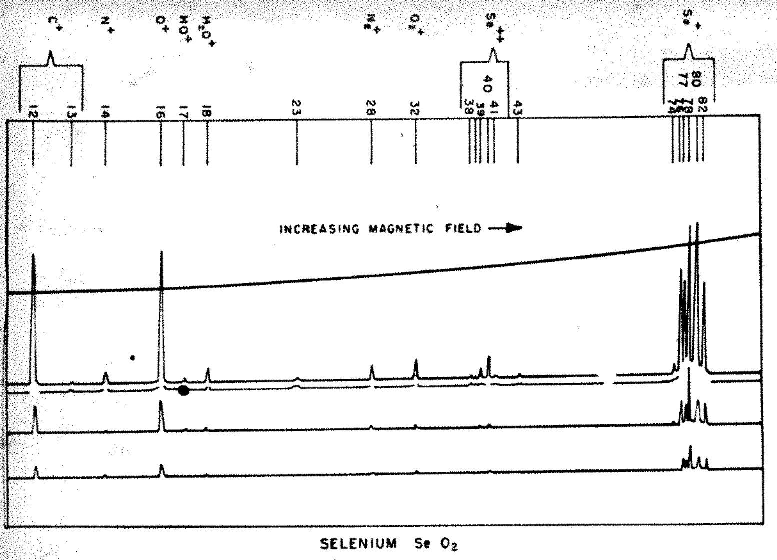

Fig. 3. Ion-beam content in the separation of selenium isotopes using selenium dioxide as the charge material

the user of enriched isotopes. Unusual compounds, pure metals, targets, etc., are often necessary.

The staff of the spectrochemical laboratory must analyse purified isotopes of all the elements so that enriched isotopes of high chemical purity and of reliable analyses are supplied the user. This involves most of the elements of the Periodic Table. An especially valuable discovery has been the adaptation of an iridium filament in the ion source, from which only a few micrograms of an unknown substance are evaporated for mass analysis.

The conversion of the uranium production mass-spectrographs to the separation of isotopes of a wide variety of masses and properties has called on physicists, electronic engineers, mechanical engineers, instrument makers and other craftsmen. The original uranium machines have been improved so extensively that the ion sources and isotope collectors used now resemble only remotely those of a few years ago.

Ion sources for uranium were subjected only to the vapour and ion products of uranium tetrachloride, whereas present ion sources must withstand the action of a wide variety of chemical compounds. The charge material ovens in uranium ion sources were heated to a maximum of 600° C., whereas for some elements now processed more than 2,000° C. is necessary. Only two isotopes of uranium, uranium-235 and 238, were separated, but in the present programme as many as ten isotopes of an element (for example, tin) are collected at one time.

Ionization potentials, process efficiencies, vapour pressures, chemical properties, natural abundances of the isotopes, the difference between adjacent isotopes of an element, and many other factors, influence the behaviour of various elements and compounds in the mass spectrograph.

Production Results

The ion currents registered at the isotope collectors differ widely among the elements. However, collector currents of a hundred milliamperes, representing the ions of all the isotopes of a particular element, are not unusual; these ions originate in a single source.

What production-rate is rep resented by 100 milliamperes of io current ? From elementary theor 1 amp.-hr. of singly charged el mental ion deposits 0·0373 gm atom of that element in the co lector. Hence, 100 m.amp. deposi approximately 26 mgm. per hr. separated lithium isotopes (masse 6 and 7), or 358 mgm. per hr. molybdenum isotopes (masses 9. 94, 95, 96, 97, 98, 100), or 772 mgm per hr. of lead isotopes (masses 20 206, 207, 208), all distribute among the collector pockets amounts proportional to the natural isotopic abundance. It interesting to note that a tot current of 100 m.amp. is equiv lent to about one billion aton moving from source to collect every billionth of a second billion = 1,000,000,000).

The following are the elemen the naturally occurring isotop of which have been successfull enriched in the large Oak Ridge mass spectrographs

Lithium
Boron
Carbon
Magnesium
Silicon
Sulphur
Chlorine
Potassium
Calcium
Titanium
Vanadium
Chromium

Iron
Nickel
Copper
Zinc
Gallium
Germanium
Selenium
Bromine
Rubidium
Strontium
Zirconium
Molybdenum

Ruthenium
Palladium
Silver
Cadmium
Indium
Tin
Antimony
Tellurium
Barium
Lanthanum
Cerium
Neodymium

Samarium
Gadolinium
Hafnium
Tungsten
Rhenium
Iridium
Platinum
Mercury
Thallium
Lead

Only europium, dysprosium, erbium, yttrium an lutetium of the rare earths, the noble gases an osmium have not been processed in the calutrons u to this time. The processing of the rare earths awai the availability of suitable charge material, and th enriching of the noble gas isotopes awaits the develop ment of appropriate isotope collectors. The solutio of both these problems is progressing satisfactoril and there appear to be no insurmountable obstacle

Typical Examples of Separations

As was stated above, all elements processed in th mass spectrograph have their individual characte istics, which result in a wide variety of performance Only a few examples will be given.

Lithium. The enrichment of the lithium isotop was initially tricky. It was difficult to maintai ionization with accelerating potential applied; th addition of a small amount of nitrogen as a 'suppor gas was of benefit. Lithium chloride as the charg material gave the largest ion beams, but its reactio or that of its dissociated components, with the met from which the ion source was fabricated, produc deposits in the ion exit slit of the ionization chambe eventually causing termination of the run. The diss ciation of lithium chloride to $LiCl^+$, Li^+ and Cl^+ io is believed to contribute to this deposition. Th addition of a few per cent lithium metal to th lithium chloride charge eliminated this trouble. A obstacles were overcome, lithium ion beams at th collectors reached several hundred milliampere Because of the large percentage mass differenc lithium-6 and lithium-7 of very high isotopic purit were obtained.

Potassium. Potassium isotopes were enriched, with mphasis on potassium-40. Continued development roduced potassium-40 of greater than 10 per cent otopic purity, its natural starting purity being only ·012 per cent. Later, using a potassium chloride harge which had been previously irradiated in the ile at Chalk River, several milligrams of 22 per cent otassium-40 were obtained. Pile irradiation had ncreased the potassium-40 content to about 0·025 er cent by the $^{39}K(n,\gamma)^{40}K$ reaction.

Iron. Iron isotopes, iron-54 (of 22 per cent natural bundance) and iron-58 (of 0·3 per cent natural bundance) are enriched to provide high-purity non-adioactive isotopes, which are then irradiated in the ile to produce radioactive iron-55 and iron-59 of igh specific activity. Specially purified graphite sotope collectors must be used to eliminate the estruction of isotopic enrichment in the collectors y natural iron contamination in the graphite.

Ruthenium, platinum, iridium and palladium. These lements have been processed, but not without considerable development. The usual compounds of hese elements decompose on heating, so vaporization y ordinary means into the ionization chamber is mpossible. Special techniques of heating the metal s high as 2,500° C. by electron bombardment rovide an abundance of ions, and many milligrams f enriched isotopes have been collected. Even at nly ten milliamperes of ion beam, as much as 0 mgm. of platinum isotopes are collected hourly.

Rare earths. The rare earth elements of atomic umbers 57–71, inclusive, present numerous problems, mong which is the obtaining of several hundred rams of their halides for ion-source charge material. ortunately, a chemical separation of the rare earth lements, using the monazite and gadolinite ores, has rovided adequate charge materials for the isotope eparation of cerium, neodymium, samarium and adolinium. Dysprosium charge material is now on and, and the rarer elements will be available with ontinued efforts.

A tributyl phosphate – nitric acid liquid–liquid ontinuous-column extraction system is employed for eparating the rare earths into their elements, and est conditions are being developed for concentrating ach element. Ion-exchange separation is sometimes sed for final chemical purification of the enriched sotopes.

From the foregoing examples it is seen that most lements present special interesting problems in the nrichment of their isotopes in the mass spectrographs. While successfully enriching the isotopes, considerable research is performed in chemistry and physics as well.

Shipments, Uses and Reports

Isotopes, enriched in the Oak Ridge mass spectrographs, were first supplied to Atomic Energy Commission Laboratories in 1946. In the following year university, industrial and other laboratories were able to obtain these isotopes for research and other uses. By the middle of 1954 more than two thousand shipments had been made, and shipments continue at the average rate of one shipment a day. Although these isotopes have been available only on loan to domestic users, a sales programme abroad has now been inaugurated.

New and valuable scientific data on such phenomena as nuclear spins, magnetic moments, hyperfine spectra, isotope shifts, nuclear energy-levels, decay patterns, neutron cross-sections, studies linked with cyclotron and other accelerator bombardments, superconductivity, beta spectroscopy, etc., have been obtained through the use of enriched isotopes.

Several enriched stable isotopes are used in the pile on a recurrent basis to produce useful radioactive isotopes. Other studies show that it is technically feasible and economically advantageous to use certain enriched stable isotopes in the cyclotron to produce radioactive isotopes not now available; initial production has begun.

Although most of these calutron-enriched isotopes are non-radioactive, the enrichment of such radioactive isotopes as beryllium-10, potassium-40, samarium-147 and others has made it possible to clarify their disintegration properties.

Not all the benefits of this stable isotope programme are in the use of the isotope products. Developments in gas discharge, ion sources, mass spectrometry, optical spectroscopy and inorganic chemistry have not only assisted in the enrichment of stable isotopes themselves, but also these developments have contributed to other atomic energy activities, particularly in the reactor field.

Many reports have been written on research made possible by having available enriched stable isotopes. In the *Physical Review* since 1946 more than four hundred such technical papers and abstracts have been published. These unclassified papers have sprung from about forty per cent of all shipments made to users outside the Atomic Energy Commission. This represents about one research report for every two shipments. No information is available on research done with the other sixty per cent of all shipments going into strictly Atomic Energy Commission studies.

The work described in this article results from the co-operative efforts of all personnel in the Stable Isotope Research and Production Division, Oak Ridge National Laboratory, and was carried out for the United States Atomic Energy Commission by Carbide and Carbon Chemicals Company, a division of the Union Carbide and Carbon Corporation.

PRODUCTION OF ELECTROMAGNETICALLY ENRICHED STABLE ISOTOPES AT HARWELL

By DRS. W. D. ALLEN, R. H. DAWTON, M. L. SMITH and P. C. THONEMANN

General Physics Division, Atomic Energy Research Establishment, Harwell, Berks

History of the British Project

IN 1946, when the U.S. Atomic Energy Commission calutrons had already been producing stable isotopes for a year, it was decided to provide facilities at the Atomic Energy Research Establishment, Harwell, for the supply of electromagnetically enriched stable isotopes to nuclear research workers both at Harwell and in British universities. Two 180° machines were built[1], the smaller prototype for the production of nuclear targets by direct deposition from the beam on to suitable backings, and the

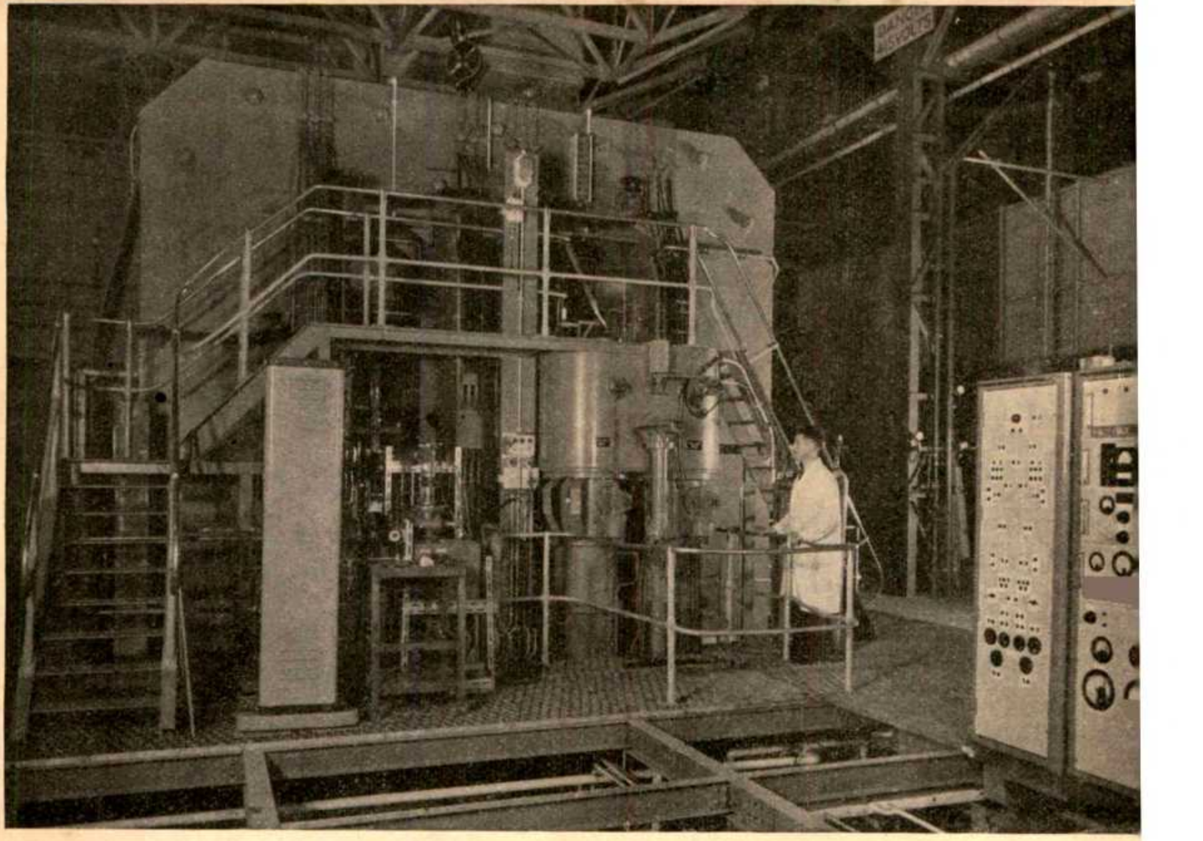

Fig. 1. General view of the large electromagnetic separator at Harwell

larger for the separation of gram-quantities of enriched isotopes.

The smaller machine started operation in 1948, and though of rather limited resolution was very useful for making nuclear targets of the lighter elements. Recently this machine was rebuilt as a 2-ft. radius 60°-sector separator for experimental work on ion sources, for separations of the rarer elements, where the source materials are expensive, and for separation of slightly active materials. This facility will be available shortly.

Early in 1950, the larger separator, which is a vertical 180°-machine of 2-ft. radius and somewhat similar in general layout to an early American machine at Berkeley, was started up. Subsequent developments were largely independent of the U.S. effort and there were numerous detailed departures from American practice; for example, in the extensive use of graphite in the source units, design of receivers, and the use of tungsten heaters for source temperatures up to 1,000° C. The machine is now being run on a production basis with shift operators.

Present Production

The outputs and enrichments obtained with the large Harwell separator are broadly similar to the results reported by the Oak Ridge workers for the smaller of their machines, and it is unnecessary here to add to the very complete account of separation experiences given in the preceding article. Owing, however, to the later British start, the inventory is smaller, though thirty-seven elements have been separated and stocks are available of most of them. Principally the lag is in the separation of the elements requiring exceptionally high temperatures, the pa ladium and platinum groups; mercury, whi requires special refrigeration arrangements; a certain elements which are not available in quanti as source materials such as rhenium and hafnium. start has been made on the rare earths, the ceriu and neodymium isotopes being already available.

Applications

Much valuable work has been done and publish by British Commonwealth and European worke with stable isotopes from Harwell. Reference ma particularly be made to the superconductivity studi on tin[2], the hyperfine spectral work at Oxford, and

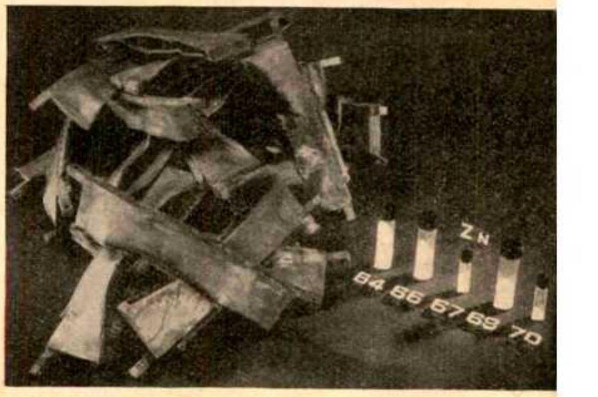

Fig. 2. Chemical processing of zinc isotopes. Photograph of the collectors used (after processing) and the bulk of enriched product as zinc oxide

umber of reaction studies too numerous to list here. arge amounts of calcium-44, iron-58 and chromium-0 have also been supplied for the production by pile radiation of radioactive tracers which have been sed in a great variety of researches So far, 570 eparate consignments or targets, ranging in size om micrograms of calcium-46 to 30 gm of iron-56, ave been dispatched to workers at Harwell and in uropean and Commonwealth laboratories The utput is now about two hundred consignments a ear and rising steadily

Particular emphasis has been laid by the Harwell roduction group on the provision of targets for uclear bombardment from the stock of stable sotopes It was found in early work that targets of lements heavier than magnesium could not be made y direct deposition in the separator because of putter, and so it was necessary to use a secondary rocedure Such procedures have the advantage, oreover, of starting with a definite amount of aterial of known purity, providing the most fficient utilization of the stocks, and being very onvenient for the users, who can request targets to uit their most varied requirements and obtain elivery within a few days For preparation of these argets a range of techniques has been adopted ncluding vacuum evaporation, electroplating, painting and thermal cracking, while special attention is aid to the recovery of residues without contamination In the course of development of these methods, useful stock of isotopic targets has also been uilt up

Some work has also been done on the preparation f gas targets by direct bombardment on to metallic oils, and by this means targets containing oxygen, itrogen or the rare gases have been made for reaction udies, while following Koch's[3] technique krypton-84 as been recovered from foils for use in spectrographic ischarge lamps

The British Thomson-Houston Co, Ltd, and the etropolitan-Vickers Electrical Co, Ltd, constructed he large separator, members of the Electromagnetic eparator Group and the Engineering Services ivision of this Establishment are responsible for peration and continuing development, while the uality of the isotopically enriched samples is hecked by the Mass Spectrographic and Spectrochemical Groups. Sales are made through the sotope Division

JOHN RAY, F.R.S. (1627–1705)

By JOAN M. EYLES

JOHN RAY, the seventeenth-century naturalist, has received more attention from the historians f science than many of his contemporaries The ay Society has published a memoir and two volumes f his correspondence, and his life and writings have ecently been treated in great detail by Dr. C E aven, to whom students of Ray and his times will lways be indebted In addition, a bibliography of is works, by Dr Geoffrey Keynes, appeared in 1951 t might seem, therefore, that little new remains to e said in this article, which commemorates the two hundred and fiftieth anniversary of his death, on January 17, 1705 Recently, however, attention has been directed to the influence of Puritanism on the development of science in the seventeenth century[1], and the occasion provides an opportunity for outlining Ray's career in this setting, as well as to offer an amendment to Dr Raven's conclusion that in geology Ray's outlook was "far in advance of all his British contemporaries"

John, the son of Roger Ray, blacksmith, of Black Notley in Essex, received his early education at the little grammar school of Braintree, two miles from his home and thirty miles south-east of the University of Cambridge At that time the school was held in what is now part of the church Ray's numerous letters throw remarkably little light on his private life, but those early grammar school days are recalled in a few dry lines in a letter he wrote to John Aubrey many years later "Neither is y^r observation universally true that the sons of labourers and rusticks are more dull and indocile than those of gentlemen and tradesmen but perchance the advantage I had of my contemporaries may rather be owing to my industry than natural parts" Ray's career was certainly built on something more than industry alone

In 1644, as a sixteen-year-old lad, he entered the University of Cambridge, supported, Dr Raven surmises, by a local charity intended to maintain "two or three hopeful poor scholars . . being also of sober and Christian conversation" At that time the Parliamentary forces had already gained the ascendency in their struggle with Charles I, and Ray's arrival at the University coincided with a period of considerable change Many Fellows, including a dozen heads of colleges who had found themselves unable to accept the Solemn League and Covenant, were being expelled from their offices During the ensuing Presbyterian regime, religion became something stern and colourless, the parish churches were stripped of their ornaments, and the prayer book and feast-days, including Christmas and Easter, were abolished

John Ray himself, however, prospered, and in 1649 was elected a Fellow of Trinity College Two years later he was accepting the usual responsibilities of a young Fellow, and acting in successive years as lecturer in Greek, in humanities and in mathematics It is true his health was not very robust An illness about the year 1650 had obliged him to rest for a while from serious study and take more fresh air, a pursuit that had directed his attention to the beauties of the Cambridge meadows, and set him to studying botany He was unable to find anyone in Cambridge who could instruct him in the subject, so turned to such books as were available, and began to collect plants for 'a little garden by his chamber"

In 1655 Ray's father died, and soon after, Ray seems to have arranged for the building of a house called Dewlands, at Black Notley, in which his widowed mother lived until her death in 1679. About this time he began to hold various College offices, and his action in building Dewlands seems that of a man who felt reasonably secure financially. He was not yet ordained, although in normal times it was required of most Fellows With the return of the bishops in 1660, this was to become a pressing question with him His earliest surviving letter, written in January 1659, indicates his views at that time "My present condition is such that I must of necessity enter into orders, or else live at great uncertainties, and expose myself to the mercy of men for my livelyhood and continuance here I am not resolved to enter into orders, if so be I stay here, but rather the contrary, it consisting not with those designes which I intend to pursue Now, if I shall bid farewell to my beloved and pleasant studies and employments, and give myself up to the priesthood, and take to the study of that which they call divinity, I thinke it were the best way to throw myself into the country, and make such provision for this world as other men doe, and make it my business to execute the priest's office" Ray was at this time engaged in preparing his catalogue of Cambridge plants, and the advantage of a country living to one so devoted to botanical pursuits is obvious, but what he had in mind when he wrote of staying in Cambridge, but not taking orders, is not clear Perhaps he had hopes of becoming a "Physic Fellow" in one of the colleges, which would have exempted him from taking orders There is little information regarding the teaching of medicine in Cambridge at that time, although several of Ray's contemporaries became physicians There had been a regius professor of physic in Cambridge since 1540, and in Ray's time this was Sir Francis Glisson, a distinguished physician, but so far as Cambridge was concerned a notable absentee He had left Cambridge at the outbreak of the Civil War and seldom visited it

In May 1660, Charles II was welcomed back to England by a people weary of internal wars and religious dissension Some measure of toleration and individual liberty was promised and expected, but the Puritans, many of whom were ministers of the Church, were soon to be disappointed We get a glimpse of the state of affairs from a letter written by Ray in September 1660 "Dr Ferne, who is made master of this colledge came down hither about the beginning of August, with 14 or 15 of the old gang . They have brought all things here as they were in 1641 viz, services morning and evening, surplice Sundayes and holydays, and their eves, organs, bowing, going bare, feasting nights" This gives a clear indication of Ray's Puritan outlook He wrote in the same letter "I have long since come to two resolutions, namely, no promise of conformity, and no orders". He must have changed his mind, or been over-persuaded by friends, for three months later he was ordained in London by the Bishop of Lincoln After this, in three different letters written in June and October of the following year, he stated his intention of leaving the College. He seems to have considered a living in Westmorland but rejected it, partly, he says, because "I find the yearly value to be lesse than it was at first represented"

In May of 1662 the Act of Uniformity received the Royal Assent and Ray knew his days at Cambridge were numbered The Act required conformity, and a declaration that the Solemn League and Covenant had been an unlawful oath, and it was obligatory for those teaching in colleges and in holy orders "I have already taken so many oathes & subscriptions as have taught me to disgust such pills", wrote Ray in 1662, and in August, "I shall now cast myselfe upon Providence and good friends Liberty is a sweet thing. I am hampered enough already, indeed more than I would have been had I foreseen this"

On August 24, St Bartholomew's Day, some eighteen hundred clergymen were ejected from their benefices for non-conformity, and Ray, who had quietly absented himself from Cambridge at the time, ceased to hold his fellowship.

In his hope for support and encouragement frc his friends, Ray was not disappointed In particul Francis Willughby, 'virtuoso' and naturalist, a form student with whom he had already made t botanical tours, rallied to his aid In 1663 Ra Willughby and two others set off on a tour of t Continent, and to gather materials for a gene natural history It is worthy of note that t universities which they first visited—Leyden, Utrec and Heidelberg—were all strongly Calvinist Willughby returned to England a year later, b Ray and another friend and former student, Phi Skippon, remained abroad until 1666 Shortly af his return, Ray made a botanical tour in Cambrid shire and Lincolnshire with Dr Martin Lister, w made some notes about it beginning "Mr Wray, M Dent & I went out a simpling"[2]

In 1667 Ray was elected to the Royal Socie and during the next five years spent much of time travelling about England, and at interv resided at Middleton, Willughby's home in Warwic shire This nomadic life was brought to an abru halt by the sudden and unexpected death Willughby, then only thirty-seven years of a Willughby, however, had looked to the future of friend, and left him an annuity of £60, which w later increased to £72 by his son, Thomas Willughb This was a generous allowance for the time Accordi to the tables of Gregory King[3], the average yea income of "lesser clergymen" in 1688 was £50, a that of "eminent clergymen" £72

Ray married in 1673, and for a few years continu to live in or near Middleton, working on Willughb collections and notes In 1679, when his mother die he was living in Essex again, and he and his w then moved into Dewlands, the house he had bu and in which he was to reside until his death. F mother's will, drawn up in Ray's neat hand in 16 shows that the blacksmith's forge was still in t family, for "all tools and utensils belonging to t shop, excepting the iron" were left to her son-in-la John Tabor, and the rest of her goods and chatte with the exception of 20*s* to the poor of Black Notl were to be divided between her son John and h grandchild Sarah Tabor[4]

From now on Ray devoted himself to the prepa tion of his botanical works, as well as the zoologi works which appeared under the name of Willughb though Dr Raven has shown they owed much Ray's own researches In 1688 an event of co siderable importance to the nation, and particula to the nonconformists, took place. James II w replaced on the throne by the Protestants Willia and Mary In 1689 the Act of Toleration was pass and this freer atmosphere was praised by Ray in Latin preface to his "Synopsis Methodica Stirpi Britannicarum", published in 1690. "Supersti has been overthrown Pure and reformed religion honoured," he wrote, and in the following year published a work entitled "The Wisdom of G Manifested in the Works of the Creation", compos largely of sermons he had delivered in Cambri more than thirty years before This was followed 1692 by a more specialized work, "Miscellane Discourses concerning the Dissolution and Chan of the World". The latter contained Ray's geologi observations and conclusions, and in later editions w entitled "Three Physico-Theological Discourses".

Ray, as Dr Raven himself states, could go on w his natural history without consciously challeng the historicity of Genesis, but in geology he enter he arena of conflict Comparisons are often unfair and ometimes invidious , but Dr Raven has stated that Ray's outlook in geology was much ahead of all his British contemporaries These contemporaries were Robert Hooke, Dr Martin Lister, Robert Plot of Oxford, and two men of a younger generation, Edward Lhwyd and John Woodward They all discussed the nature and origin of fossils (Lister and Lhwyd in letters to Ray), and it is to this point that Dr Raven gives most attention Hooke, in time as well as in accurate and penetrating commentary, takes precedence of them all, for his statement about fossils in "Micrographia" (1665), though short, is to the point Some account of Hooke's geological ideas, and the period to which they rightly belong, has been given by W N Edwards[5] and by A P Rossiter[6] Hooke's geological observations, in addition to those in his "Micrographia", are found in his Cutlerian Lecture, "De Potentia Restitutiva" (1678) and in his "Posthumous Works" (1705) The latter includes the text of two discourses delivered to the Royal Society between June 17, 1667, and September 1668 In none of these does Hooke waver from his view that fossils were genuine remains of once living creatures Ray, on the other hand, felt obliged (as he wrote in a letter to Lhwyd in November 1690) "to settle in a middle opinion, that some are of one kind, some of another" Lhwyd answered in the same month and in the same vein "I find in myself no sufficient ability or confidence to maintain either opinion" It is not denied, and there is abundant evidence, that Ray was anxious to believe that fossils were remains of once living things , but he had a fundamental reason for this, made clear in some pages (unnumbered but following p 162) first inserted in the second edition of the "Discourses" (1693) "For," he wrote, "if we adhere to their Opinions who hold them [that is, the fossils] to have been original Productions of Nature, in imitation only of the Shells and Bones of Fishes We put a Weapon into the Atheists hands" This weapon, which Ray discusses at some length, was the argument that if fossils were mere sports of Nature, produced without reason or function, then living animals, too, could be produced without "Counsel or Design". Such an argument, difficult for the modern reader to appreciate, struck at the very core of Ray's creed of divine design in Nature For this reason, above all others, he was constrained to support the view that fossils had once been living things

Two arguments against this, however, Ray had great difficulty in answering One, which concerned the Deluge, will not be discussed here , the other was the fixity of species That species might disappear he had thought "highly improbable" , but many of the fossils then being found could not be matched with living forms, and he could only hazard "that there may be some of them remaining some where or other in the Seas" Hooke had accepted the implication of extinct species , but it was this implication, more than anything else, that seems to have driven Ray to decide finally in favour of an inorganic origin for fossils Dr Raven has called this a recantation , but it was rather a reluctant conclusion from the evidence interpreted in the light of Ray's beliefs, evidence that had steadily accumulated as more and more ammonites and Coal Measure plants, which had no known modern equivalent, were discovered by the untiring efforts of Lhwyd, Woodward and other collectors We can sympathize with Ray in his difficulty , but we must not overlook the clear thinking and bold imagination of Hooke. Thus, there seems no room for doubt that it is Hooke rather than Ray who deserves Dr Raven's encomium It must be stressed, however, that the advances in geology were made not by the theorists but by field-workers The latter include John Woodward, whose theories were weak, but who insisted on the importance of accurate field records

The last fifteen years of Ray's life were spent in constant pain and illness, but his industry never slackened He was indeed, as H B de Saussure wrote in 1779, "le Naturaliste le plus universel que l'Angleterre ait produit"

OBITUARIES

Prof H S Carslaw

THE death occurred on November 11 at the age of eighty-four of Horatio Scott Carslaw, emeritus professor in the University of Sydney, and Fellow of Emmanuel College, Cambridge, professor of mathematics in the University of Sydney during 1903–35 Carslaw held the degrees of doctor of science of Glasgow and Cambridge, and the honorary degree of doctor of laws of Glasgow

Carslaw served the University of Sydney through a period of great expansion He had precisely that balance of qualities which best fit a man to raise a small department, not very different from a 'sixth form', to a university school of mathematics with a world-wide reputation for its published work and for the quality of its graduates He had a vigorous personality of the type around which legends collect, he was a mathematical scholar of distinction with a gift for clear exposition, and he was enthusiastic in his mathematics and aroused enthusiasm in his students

During his tenure of the chair, the University of Sydney grew from a family affair of a few hundred students to a complex organism of four thousand students in ten faculties In particular, this period saw the rise of the Faculties of Science and Engineering In large measure the high standing of Sydney engineering graduates was due to Carslaw's influence on the shape of the course His locally famous 'little book' bears the title "An Introduction to the Infinitesimal Calculus Notes for the Use of Science and Engineering Students". His first- and second-year pass courses had very much the needs of these students in mind. The book is one of those that a lecturer likes to use as a basis for a lecture course , the text is little more than a record of leading results, there are plenty of examples, and the lecturer has scope for his own elaboration and development of the subject

Carslaw played a large part in the development of the State (New South Wales) secondary education system, in particular in the formulation of the mathematics syllabus and its examination at the Leaving Certificate Between 1911 and 1916 he published a series of articles and reports, under such titles as "The Teaching of Elementary Mathematics" and "Secondary Education in Australia", which have done much to give direction and purpose to mathematical teaching in the State right up to the present time

Carslaw's interests in mathematics were wide, as a list of his principal works shows "An Introduction to the Theory of Fourier Series and Integrals and the Mathematical Theory of the Conduction of Heat", first published in 1906 and rewritten and published as two separate volumes in 1921, "Plane Trigonometry" (1909), "Elements of Non-Euclidean Plane Geometry and Trigonometry" (1916), and "Operational Methods in Applied Mathematics" (1948, with J. C Jaeger) Each of these contains work which is Carslaw's own contribution to the subject The earlier works were many times reprinted and were standard text-books for more than a quarter of a century The "Fourier Series" and the "Conduction" were translated into Japanese, and the "Conduction" was reprinted and widely circulated in the United States during the Second World War

From 1916 onwards he published from time to time articles in the *Mathematical Gazette* and elsewhere on "Progressive Income Tax", and was consulted by the Commonwealth Treasury on the formulæ to be adopted, the aim of the formulæ being to give a continuous increase of rate of tax over quite a long range of incomes, such formulæ were in use until quite recently.

After retiring from the chair of mathematics in Sydney in 1935, Carslaw spent all his time on his small orchard property at Burradoo, eighty miles from the University, and only rarely went to the city But his interest in mathematics continued unabated, until within the past three years failing sight made it impossible for him to continue After the War, while in his late seventies, he had several years of fruitful collaboration with one of his students of twenty years earlier, now Prof J C Jaeger The fruits of this collaboration were the revised third edition of the "Conduction", and the "Operational Methods" mentioned above

In 1907 Carslaw married Ethel Maude, the daughter of Sir William Clark, but she died within the year Thereafter, Carslaw took little part in the social life of the University of Sydney, but he contributed with his characteristic vigour and vivacity to all other phases of University activity T G Room

Sir Frederick McMaster

Sir Frederick Duncan McMaster died at his home at Dalkeith Station, Cassilis, N S W, on November 28 He was one of Australia's best-known pastoralists and a prominent studmaster One of his main interests was breeding merino sheep, and he gradually built up the world-famous Dalkeith Stud Sheep from this stud won many prizes in competition, and at one time a ram from this stud held the world's record for the greatest price

Sir Frederick was interested in and supported many plans for the improvement of Australia's pastoral industry He was always anxious and willing to help the small man On one occasion he presented the Government with five hundred merino rams valued at £4,000 for distribution to small-scale farmers who had been badly affected by the depression He was also interested in beef-cattle breeding His success was well recognized by many prizes at the Sydney Royal Show

In 1929 the Prime Minister made an appeal fo public support for research into Australian primar industries Sir Frederick responded by the presentation of £20,000 for the erection of a laboratory fo the investigation of animal health problems Thi laboratory, known as the McMaster Animal Healt Laboratory, was erected for the Commonwealt Council for Scientific and Industrial Research at th University of Sydney A great deal of invaluabl research has been done at this laboratory When i became known to Sir Frederick in recent months tha the McMaster Laboratory was in urgent need o additional space, he spontaneously instructed hi solicitors to arrange for Commonwealth bonds to th value of £52,800 to be made available to the Universit of Sydney for the erection of a wing to the Laboratory

Sir Frederick took a keen interest in research particularly in agriculture He was a member of th N S W State Advisory Committee of the Commonwealth Scientific and Industrial Research Organization for many years He provided facilities on hi own properties for scientists to carry out field-work and leased 2,000 acres of Hinchinbrook Estate t assist scientific research He was a keen observe and co-operated with the Meteorological Office i obtaining and keeping complete meteorologica records He was a prominent member of the Roya Agricultural Society of New South Wales and als an honorary life member of the Royal Agricultura Society of England

Sir Frederick was born in 1873 and was educate at the Sydney Grammar School In 1934 he wa created a knight bachelor in recognition of his grea services By his death, Australia has lost a grea pastoralist, a keen supporter of scientific work, an a generous benefactor J. R A McMillan

NEWS and VIEWS

Sunspots of the New Cycle

The Astronomer Royal reports the appearance o two sunspots that are the first sizable spots of th new eleven-year cycle Particulars of these are a follows

Date on sun's disk	Central meridian passage (U T)	Latitude	Are
Jan 2–14	Jan 8 1	20° N	10
Jan 7–19	Jan 13 1	36° N	80

The areas were measured on January 9, the previou days having been overcast The unit of area is one millionth of the sun's hemisphere In addition to th above two spots, an earlier one (probably of comparable size) was observed at Edinburgh on Decembe 30 during the overcast period at Herstmonceux Thi spot group, in latitude 24° south, must have develope suddenly between December 28 and 30, and woul have passed off the sun's disk on January 5

The sunspot cycle, with its great peak of activit in 1947, presumably ended just before the middle o 1954 There has been the characteristic overlap i latitude of the old-cycle spots petering out i equatorial regions and the increasing incidence of th small new-cycle spots in latitude 20°–40° An remaining doubt concerning the epoch of minimu significant to 1954 4 is now removed by th appearance of these definite spot groups, indicatin that the new eleven-year cycle has now definitel begun.

illiam Sharp (1805–96)

To his medical colleagues, William Sharp, who was rn at Armley, near Leeds, one hundred and fifty ars ago, on January 21, 1805, was known as a gorous champion of homœopathy, but he is also membered as a pioneer of science teaching in public hools in Britain and also of the local museum lucated at Wakefield Grammar School and at estminster School, he was articled to an uncle, a adford surgeon, in 1821 After attending the nited Borough Hospitals in London, he was licensed the Society of Apothecaries in 1826 and became member of the College of Surgeons of England in e following year In 1829 he was elected surgeon the Bradford Infirmary, and succeeding his uncle 1833, he had one of the largest general practices the West Riding of Yorkshire He founded the adford Philosophical Society and served as its st president At the Birmingham meeting of the itish Association in 1839, he advocated the estab- hment of local museums for the display of exhibits particular interest to the district Shortly after- rds he was elected a Fellow of the Royal Society hile in practice at Hull, he lectured on chemistry the Hull and East Riding School of Medicine, and terwards was responsible for the introduction of ence teaching at Rugby School—an example soon lowed by other public schools Sharp wrote some ty tracts on homœopathy Stressing the opposite- tions of large and small doses of the same drug, tried to reconcile homœopathic and allopathic ching One of his best-known works was "Thera- utics founded upon Organopathy and Antipraxy" 386) Sharp received the M D from the Archbishop Canterbury in 1856 and died at Llandudno on ril 10, 1896, aged ninety-one

ief Librarian of the Commonwealth Scientific and Industrial Research Organization

Miss E L Archer, chief librarian of the Common- alth Scientific and Industrial Research Organiza- n, Melbourne, has retired Miss Archer has had a nger association with the Organization and its decessors than any other member of the staff e has built up the library system of the Organ- tion over a period of thirty years, and her re- nsibility extends beyond the management of the rary at head office to include the supervision of re than thirty divisional and sectional libraries tributed through every State of the Common- alth of Australia She has done much to raise the tus of librarians in Australia and to gain recog- ion for library work as a specialist profession, and s the first woman federal president of the Aus- lian Institute of Librarians in 1948 Miss Archer s born and educated in Melbourne, and holds the gree of M Sc of the University of Melbourne with nours in botany She made a special study of the of the Universal Decimal Classification and intro- ced it into the libraries for which she was responsible er a visit to Europe, including Great Britain, ing 1936

ding in Plant and Animal Taxonomics

Two meetings have been held at the Chemical- ological Coordination Center, National Research uncil, Washington, D C, "to explore the poss- lity and desirability of developing a unified system coding plant and animal taxonomic entities" fortunately, no samples of proposed systems of coding are given Apparently the idea is that every taxon shall be given a 'code number' built up of figures indicating designation, ordinal relationship, and description Since taxonomy is dynamic, not static, with, one hopes, its methods and results constantly progressing, it is difficult to envisage a code that would not require frequent revision However, supplementary data may clear up some of the doubts that arise when one envisages an elaborate scheme in practice Taxonomists wishing for further information should apply to Dr G Congdon Wood, Chemical-Biological Coordination Center, National Research Council, 2101 Constitution Avenue, N W, Washington 25, D C, U S A An outline scheme for taxonomic coding was given, apparently quite independently of the meetings referred to above, in *Chronica Botanica*, 12, 211 (1951)

Stalk Borers of the Tropics

The stalk borers of graminaceous crops in the tropics are chiefly lepidopterous caterpillars In the aggregate they levy a heavy toll on the world's food supply, but because their action is insidious, occurring year after year to a varying extent, but without such spectacular effects as the locust may bring about, their importance is often overlooked and effective action is seldom taken Indeed, in most regions there is no reliable assessment of the damage they cause Moreover, the prior attention of entomologists has usually been given to insect pests of plantation crops in which the prospects of early control are generally more promising At the present day two factors are tending to remove this indifference the insistent demand for increasing the food production of the world, and the development of synthetic insecticides which may prove applicable in tropical peasant agriculture It is therefore timely that Dr W P Jepson should have produced a "Critical Review of the World Literature on the Lepidopterous Stalk Borers of Tropical Graminaceous Crops" (pp vi+127. London Commonwealth Institute of Entomology, 1954, 15*s*) Here, for the first time, all the available information on this subject has been brought together

Archæology of Deneholes

The "Proceedings" for 1954 of the Croydon Natural History and Scientific Society contains interesting articles on deneholes and on Croydon itself Deneholes are excavations in underlying chalk reached by vertical shafts through the overload. They often consist of a number of chambers, and the excavations were carefully and scientifically done The vertical shafts—sometimes 30–40 ft deep—can be dangerous and so have frequently been plugged It sometimes happens that the plugs themselves collapse into the underlying cave, as has recently occurred at Waddon This gave an opportunity for investigation before the plug had to be reinstated. The age of the deneholes seems to be pre-Roman, and they are probably of the Iron Age Many explanations have been given as to why they were made, but none is satisfactory Underground granaries or stores have been suggested, or pits for obtaining chalk for agriculture, but, if the latter explanation be the correct one, why have they been so carefully made? Drainage sumps, places of worship, underground dwellings and secret refuges, or burial places have all been suggested from time to time It would seem clear, however, that some connexion must exist between these artificial caves and the earth-houses of northern Scotland But unfortunately we do not really know why these latter were made, either

Making and Measuring Gauges

DURING the Second World War a booklet dealing with the making and measuring of gauges was prepared by the staff of the National Physical Laboratory, Teddington, as a war-time aid to firms who were entering the field of gauge-making for the first time, and a new and revised edition of this booklet has now been issued as No 5 in the series of "Notes on Applied Science" under the title of "Gauge Making and Measuring" (pp 79+1 plate London H M S O , 1954 , 3*s* net) The Notes touch upon both the manufacture and measurement of gauges and, in addition, include descriptions of measuring equipment suitable for this class of work. Only the simpler types of plain and form gauges are considered, as screw gauges are adequately dealt with in No 1 of the series. Much information which should be already familiar to experienced gauge-makers is included , but several novel topics are also discussed. The contents consist of four parts. Part 1, which is of a general and introductory nature, refers to the general requirements of gauges as to marking, dimensions, hardness and finish in accordance with British Standard specifications The serious errors that can arise in the measurement of gauges as a result of thermal expansion are particularly emphasized Part 2 deals with the selection of suitable steel for gauges and with the detailed techniques for machining, hardening, stabilizing and grinding the blanks, and with other workshop methods, some novel, involved in gauge-making Parts 3 and 4 are devoted to measuring apparatus commonly used in gauge-making and describe bench micrometers, vertical comparators and using light in measurement. "Gauge Making and Measuring" is a valuable addition to the literature on metrology and should be of particular assistance not only to gauge-makers but also as a text-book for students who are studying metrology as a subject in the National Certificate Examinations

Chemical Abstracts: New Greek Journal

THE Centre of Bibliographical Investigation in Athens has begun to publish a monthly abstract journal, *Chemical Research*, dealing with pure and applied chemistry This contains abstracts in Greek of papers published in journals of all countries , but there is an appendix, which in the copy received is in English, French and Italian, of abstracts of papers published in Greece This appendix will serve to direct attention to publications of Greek chemists, and, since one of the abstracts is of a doctoral thesis of the University of Athens, it is likely to refer to publications which could otherwise be missed The journal is published from 44 Charocopou Street, Kallithea, Athens

Earthquakes during May–September 1954

FORTY-SEVEN earthquakes having instrumental magnitude 6 or greater occurred during May–September 1954 The greatest (magnitude 7¼) occurred on September 17 in the region of the Fiji Islands The earthquake with the deepest focus (600 km) also occurred in the Fiji Islands region on September 15. Earthquakes were reported as having occurred in Europe as follows Greece and adjacent countries (5), Switzerland (7), Spain (5), Jan Mayen Island (3), Germany (1), Belgium (1) and Norway (1).

Textile Institute: Medal Awards

THE following awards have been announced by
Textile Institute the Institute Medal, awarded
distinguished services to the textile industry
general and to the Institute in particular, to Mr
Crossley, managing director of the Yorkshire Dye
and Proofing Company, Ltd , Middleton, Lan
and to Dr P W Cunliffe, research manager of
British Cotton and Wool Dyers' Association, Lt
the Institute Service Medal, awarded in recognit
of valuable services to the Textile Institute, to
E J D Poole, senior principal technical officer
the Wool Industries Research Association , Mr
Morris, textile chemist with Allied Colloids (Ma
facturing) Co , Ltd , and Mr J R S Goodall,
Stockport

N.Z National Research Fellowships (1955)

THE Minister of Scientific and Industrial Resear
New Zealand, has awarded the four National Resea
Fellowships to be taken up during 1955 as follow
Dr H C. Clark, junior lecturer in the Chemis
Department, Auckland University College, who
carry out research at the University of Cambridg
Mr H V Brewerton, a chemist at the Domin
Laboratory (N Z Department of Scientific a
Industrial Research) at Wellington, who will work
the chemistry of the extractives of New Zeala
timbers at the University of Nottingham , Mr P
Fitzgerald, a plant breeder at the Crop Resear
Division of the N Z Department of Scientific a
Industrial Research, who will work in the Genet
Department, University of Adelaide , Mr J
Lovis, of the Department of Botany, University
Leeds, who will work in Canterbury Univers
College These Fellowships are offered annually
suitable applicants with postgraduate experience
scientific research to enable them to study at N
Zealand or overseas institutions Each Fellows
has a value of £600 a year, an additional £100 a y
being paid to a married man Grants of up to
for books, fees, etc , and up to £150 for travel
also paid The tenure of a Fellowship is for one y
with provision for an extension by a further y
where such extension is justified.

Conference on Mass Spectrometry

THE Third Annual Conference on Mass Spect
metry under the sponsorship of Committee *E*-14
the American Society for Testing Materials will
held during May 23–27 at the Mark Hopkins Ho
in San Francisco, California All aspects of
theory and application of mass spectrometry will
covered Titles of papers should be submitted
February 15 to Mr William Priestley, jun , Stand
Oil Development Co , Box 121, Linden, New Jers
There will also be an exhibit of mass spectrome
equipment, information about which can be obtai
from Dr J. G Hutton, General Electric Co , 1 R
Road, Schenectady, New York

Colonial Service: Recent Appointments

THE following appointments have recently b
made in the Colonial Service J S Blackl
(agricultural officer, Sarawak), agricultural offi
Northern Rhodesia , L H Brown (agricultu
officer, Kenya), provincial agricultural officer, Ken
T N. Greeves (senior agricultural officer, North
Region, Nigeria), deputy director of agricultu
Sierra Leone , N M Lucie Smith (assistant dire
of agriculture, Gold Coast), director of agricultu

auritius, A Storrar (agricultural officer, Kenya), ovincial agricultural officer, Kenya, B. C Wills gricultural officer, Northern Rhodesia), assistant rector of agriculture (field services), Kenya, P A llison (senior assistant conservator of forests, igeria), conservator of forests, Western Region, igeria, H B Burgess (senior assistant conservator forests, Nigeria), conservator of forests, Western egion, Nigeria, J W Henderson (assistant conrvator of forests, Gold Coast), senior assistant nservator of forests, Gold Coast, L M Bear eologist, Kenya), geologist, Cyprus, A M Guennel ssistant director), deputy director of the Geological irvey, Tanganyika, A W Peers, agricultural ficer, Kenya, P B. Harris, agricultural officer, orthern Region, Nigeria, H E G Morgan and . F A Murfitt, agricultural officers, Sierra Leone, B Lyons, chemist, Department of Chemistry, ngapore, O Von Knorring, chemist, Geological irvey Department, Federation of Malaya, R ross, fisheries officer, Northern Region, Nigeria, . B Meecham, fisheries officer, Gold Coast, T M ow, assistant conservator of forests, Northern hodesia, R H Graham, assistant conservator of rests, Western Region, Nigeria, R G Lowe, sistant conservator of forests, Northern Region, igeria, W D. Clayton, specialist officer (ecologist), ederation of Nigeria, J. W. Millbank, scientific ficer, East African Agriculture and Forestry esearch Organization, East Africa High Commison, P F Prevett, scientific officer, Sierra Leone, Quarterman, scientific officer, East Africa High mmission, F Raw, senior scientific officer ntomologist), West Africa Cocoa Research Initute, Gold Coast, P B. H Tinker, scientific ficer (chemist), West Africa Institute for Oil Palm esearch, Federation of Nigeria, T Williams, plant thologist (scientific), North Borneo

nnouncements

We regret to announce the death of Sir Arthur Keith, R S, master of the Buckston Browne Research arm, formerly Hunterian professor in the Royal ollege of Surgeons, on January 7, aged eighty-eight

The Paris Academy of Sciences has made the llowing awards, among others Lavoisier Medal to rof F Joliot and Mme Joliot, on the occasion of e twentieth anniversary of the discovery of artificial dioactivity, Henri Poincaré Medal to Prof G aliron, for distinguished work in mathematics, rix Le Conte (350,000 francs) to M Lucien Bull, of e Marey Institute, for his work in devising equipent for ultra-rapid cinematography, clinical electrordiography, application of the electric spark to the nematography of shock waves, etc., Prix Osiris ,000,000 francs) to Emile Borel, for distinguished ork in mathematics

Dr Irvine C Gardner, chief of the Optics and etrology Division of the U S National Bureau of tandards, has been awarded the Frederick Ives edal for 1954 of the Optical Society of America, for istinguished work in optics and his leadership of hers, which have "done much to stimulate progress geometrical optics in this country". This Medal, warded biennially until 1951 and annually since en, was endowed in 1928 in honour of Frederick es, who was distinguished for his pioneer conibutions to colour photography, photo-engraving, ree-colour process printing, and other branches of pplied optics.

The Council of the Institution of Electrical Engineers has elected Mr J R Beard to honorary membership of the Institution for his distinguished services to the profession, more especially in the field of the transmission and distribution of electricity and for his valuable services to the Institution The thirty-third award of the Faraday Medal of the Institution has been made to Sir John Cockcroft, director of the Atomic Energy Research Establishment, Harwell, for the conspicuous services he has rendered to the advancement of electrical science, and for his distinguished work in the field of nuclear physics and the development of power from nuclear sources

The Road Research Laboratory (Department of Scientific and Industrial Research) is to hold open days this year at both the Materials and Construction Division at Harmondsworth, Middlesex, and the Traffic and Safety Division at Langley, Bucks, on May 12 and 13 The Scottish Branch of the Laboratory at Thorntonhall, near Glasgow, will be open to visitors on June 2 and 3

The fourth annual conference of the Aslib Aeronautical Group will be held at Cranfield during April 1–3 The main discussion will centre on classification, and co-operating in the conference will be the Classification Research Group Full particulars may be obtained from C W Cleverdon, Librarian, College of Aeronautics, Cranfield, Bletchley, Bucks

A symposium on molecular structure and spectroscopy will be held in the Department of Physics and Astronomy, Ohio State University, during June 13–17 There will be discussions of the interpretation of molecular spectroscopic data as well as of methods for obtaining such data In addition, there will be sessions devoted to those phases of spectroscopy of current interest Further information can be obtained from Prof H H Nielsen, Department of Physics and Astronomy, Ohio State University, Columbus 10, Ohio

W G Pye and Co, Ltd, Granta Works, Cambridge, have issued a new illustrated catalogue, Catalogue *J*, which supersedes all previous issues and includes only those instruments which are in current production The instruments described are grouped into eight sections electronic and associated instruments, including geophones, pH meters and Pirani and ionization gauges, galvanometers, electrometers and accessories, general physics, mostly for student use and including many pieces of apparatus designed by the late Dr G F C Searle, magnetic instruments, measuring microscopes, cathetometers and accessories, miscellaneous items, including switches and clocks, potentiometers, and resistance bridges and boxes

The Medical Research Council invites applications for a further series of fellowships in clinical research of the value of £850 a year, tenable at centres in the United Kingdom during the academic year 1955–56 These fellowships are ordinarily restricted to medically qualified British subjects resident in the United Kingdom Applications must be sponsored in each case by the head of the appropriate department in the candidate's university or medical school Forms of application for these fellowships may be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, London, S W 1, to whom they must be returned not later than March 1.

INDUSTRIAL MANAGEMENT IN EUROPE

UNDER the auspices of the British Institute of Management, an outstandingly successful conference was held at Torquay during October 20–23. This was attended by 1,070 delegates, 350 of whom came from European countries as far afield as Yugoslavia and Turkey in the east, Finland in the north and Malta in the south In addition, there were fifty delegates from Commonwealth countries, North and South America, the Philippines and Iceland The largest single delegation outside the United Kingdom came from Germany, with the Netherlands and Scandinavia second and third

The papers covered all aspects of management, and one of the most interesting was presented by M Pierre Bezier, directeur des méthodes mécaniques, Régie Nationale des Usines Renault, Billancourt, who spoke about the implications for management of automation, this is particularly important for industrialists who have to instal and develop the means necessary to launch mass-produced products The acquisition of all the machines necessary for a new manufacturing programme, according to M Bezier, is only possible if a machine-tool industry is in existence which is capable of satisfying a heavy demand within a reasonable delivery time, and such an industry can only exist if a sufficiently large group of customers is available to ensure a steady flow of orders and regular and sufficient work These conditions obtain in the United States, where the domestic market is able to take all the output of the automobile industry and a large part of the domestic equipment industry such as washing machines, refrigerators and plumbing and heating equipment European factories generally have to fall back on American manufacturers or on local industry for their machine tools Most British motor-car factories are in this position

Experience in the use of special machines has made it possible to lay down certain simple rules which can reduce the consequences of unforeseen breakdowns, great importance is attached to the standardization of equipment Equipment should be sufficiently strongly designed to withstand several years of intensive operation, it should also be 'flexible' It is particularly useful to avoid units with a short stroke, as this can cause difficulty when tools are changed, 12 in travel should be considered as a minimum

Many machine builders have remained faithful to hydraulic controls, M Bezier prefers electromechanical systems, the principal advantage of which is that they can be applied equally to drilling, tapping or milling cycles When a piece of equipment goes out of service as a particular model is withdrawn, it is possible to turn it to some other kind of work When a machine begins to show signs of wear and it becomes difficult to continue with precision work, drastic overhauls must be carried out The standardization of machine elements enables this to be completed in a few days

For a long time it was considered that the personnel operating expensive and complicated machines ought to be provided with extensive technical training, and that it would be necessary to envisage a high proportion of supervision and maintenance personnel These two fears have been shown to be without foundation

Discussing the application of psychology to industrial training, Mr A. T. Welford, director of the Nuffield Research Unit, Cambridge, stated th whereas studies of learning form a very large part experimental psychology in the laboratory, little u has been made of them in problems of industr training This is a field ready for developmer First, there is much recent experimental eviden that performance after training is better if t training has been on a task a little more difficult th that for which the man is being prepared Secon there appears to be a growing tendency for t ability to state in words what has to be done to taken as a criterion of proficiency at a task Ma skills are not easily put into words, and it seer possible that trying to do so may, in fact, distort t emphasis upon particular features and so tend disrupt rather than assist the free exercise of t skill

The third point about training is that the way which a task is performed the first time it is met c sometimes have a profound influence upon how it performed afterwards In other words, it is mc difficult to modify a method of work already lear than to learn it in the first instance—a principle w known in games This means that attention to t initial stages of training is very important, it better that a complex operation should be brok down into a number of very small units, each which can easily be mastered on its own, althou together they would be very difficult Rapidity training is not always the best criterion of its succe and more time spent during training may be reward by better performance later, which in turn may le to greater satisfaction in work and lower turnov of labour

Another outstanding paper was that read by Pr G Lehmann, director of the Max-Planck-Institut f Arbeitsphysiologie He discussed the physiologic principles in the rational organization of work an *inter alia*, showed that, in building, it has proved be more economical to use large-sized bricks of weight of 20–30 kgm made of a material with low specific gravity rather than the smaller ones nc used With them it is possible to erect a bri surface six times as large as one built with norm sized bricks at the same cost of energy The reas for this remarkable state of affairs is that often mo than 90 per cent of the total energy spent is us not for the transport of work pieces and tools b for the movements of the human body The emplo ment of big and inert limbs for the transport of small brick is uneconomical Fewer movements wi heavier loads are therefore more advantageous

Prof Lehmann showed that the effect of re pauses is much greater if they are spread even over the working day The best results are achiev if the pauses are taken in relation to the physiologic performance curve over the day, that is, if the are fewer rest pauses in the morning when the m are at their best, and more after the beginning work, or around midday and evening Generall many short pauses are more effective than a few lo ones of the same total duration This follows fro the fact that recovery follows an exponential curv setting in rapidly and continuing more and mo slowly

Short obligatory rest pauses should be establish in industries If on observing physically light wo one finds that 15 per cent of the time is spent eal pauses, and a further 15 per cent is spent for ancillary work, part of which, too, stands for hidden est pauses, it might seem useless to introduce further obligatory rest pauses; results show the contrary. If for every hour an obligatory pause of five minutes s introduced, the number of arbitrary pauses diminishes, together with the time spent on ancillary work. The gain in effective working-time—and therefore production—exceeds by far the loss caused by the introduction of the short obligatory pauses.

For the management of a plant it is important to know whether the limiting factor of production is to be found in the worker or with the technical equipment. Sometimes output does not rise, or even diminishes, after some machine has been replaced by a more efficient one. The reason may be that the worker has lost some of the rest pauses which had been essential for his performance.

The closing address was given by Dr. D. U. Stikker, Netherlands Ambassador to Great Britain, who suggested that in examining responsibility for social questions the task of management is really enormous. Wherever the principle of social responsibility is accepted, profits are increased; but where these principles are not accepted, unrest prevails and all the devices of efficiency are of no avail. In Holland, during the Second World War, when the country was being stripped of its wealth, there was a small group of people—some trade union leaders, ome managers and a few politicians—who saw quite learly that the only way to tackle the problem of econstruction after the War was by the closest o-operation between labour, management and the Government. At that time management accepted its ocial task and so did labour, and together they reated a new institution known as the Foundation f Labour, a body which has done much to build up the prosperity of Holland. This experiment is nprecedented—an experiment in which organized abour and management came together on a permanent basis in one institution to produce a national wage policy in an endeavour to keep price-levels down and to study plans for social security which were submitted to the Government. The years of social peace that followed the setting up of this new nstitution can be illustrated by the decreasing gures of working days lost through labour disputes. n 1953, with a population of 10,000,000 people, not more than 30,000 working days were lost; in 1954 here were practically no further strikes and it was deemed unnecessary to publish figures concerning abour disputes. As this institution came into being n the initiative of management, it would seem that management, at the present time, can play a completely different part from the old days, when it was elieved that profit-making in itself was a sufficient ontribution to the national welfare.

Looking at the different systems in existence in he world to-day, Dr. Stikker said that it is possible o distinguish between three of these. The first ystem is a crude one of unrelenting warfare between wo parties. That system is defended at the present moment in the United States, where a group of ociologists and trade union leaders maintain that he bitter struggle between the parties in itself produces a high standard of living and high efficiency. They claim that the European system of social esponsibility creates conditions of stagnation, low wages and low productivity. They believe that a erce struggle will create efficiency, effective man-our saving devices and highly paid labour. If this system has any value at all, such a system can only exist in a country with an expanding economy, with a highly mobile labour force and with great natural resources. The second system is the system behind the Iron Curtain, a system of complete State control over labour and management, where no disputes are possible because the answer to every dispute is a slave camp. Such a system cannot be accepted by anyone who believes in human dignity and freedom. The third system is the one which occurs mostly in Europe, a system of negotiation; where this does not produce the right result there is the alternative of a panel solution by arbitration. If this is the right system at the present moment, there is no reason for complacency. While this system may be acceptable to management and to the trade union leaders, it may not be acceptable by the rank and file.

Management in Europe should not be content, said Dr. Stikker, with the negative task of preventing strikes. It should look for the positive task of increasing productivity. Here every individual manager has a part to play because industrial unrest is not always due to frustrated wage claims, although that may well be the reason for its origin. Management should not be on the alert only for discontent; it should strive to create an atmosphere where a man derives satisfaction from, and at the same time gets a little praise for, doing a good job. This idea of social responsibility is not new; but to put it into effect is another story. Management could not give a greater contribution to prosperity than by a universal acceptance and application of this principle of social responsibility.

T. H. HAWKINS

DETERMINATION OF VITAMIN A IN NATURAL PRODUCTS AND IN MARGARINE

AT a joint meeting of the Oils and Fats Group of the Society of Chemical Industry, and of the Society of Public Analysts, held at Burlington House, London, on December 1, papers were read on the determination of vitamin A in natural products and in margarine.

Prof. R. A. Morton, in a communication with F. Bro-Rasmussen, recalled that for some years the unit of vitamin A activity was defined as that exhibited by 0·6 μgm. of the precursor, β-carotene. Vitamin A itself was later crystallized and its activity was found to be 3·3 × 10^6 units per gm. The International Unit was re-defined as the activity of 0·3 μgm. of pure crystalline all-*trans* vitamin A or the equivalent weight of vitamin A acetate. Vitamin A is usually determined by the intensity of absorption at the maximum (near 325 mμ) in its ultra-violet absorption spectrum, and a conversion factor of 1,900 (see Table 1) has official sanction internationally as well as in pharmacopœias.

It was inevitable that the reference substance should be all-*trans* vitamin A (acetate), and indeed much of the demand for vitamin A, for example, for the fortification of margarine, is now being met by the synthetic all-*trans* acetate.

When vitamin A is determined by its ultra-violet absorption, the spectrophotometric measurements must be made on solutions in which vitamin A is responsible for a large proportion of the intensity of absorption in the region 300–350 mμ. This condition

Table 1 VITAMIN A ALCOHOLS

	All-*trans* Vitamin A_1	Neovitamin A_1	Vitamin A_2
Potency (I U /gm) × 10^6	3 33*	2 66[3]	1 33[4]
λ_{max} mμ in *cyclo*-hexane	326	328	351
E(1%, 1 cm) at λ_{max}	1,745[2]	1,650[5]	1,350[6,7]
E(1%, 1 cm) at 326 mμ	1,745	1,615	1,050
Conversion factor (that is, potency – E(1%, 1 cm) at 326 mμ)	1,908	1,647	1,267

* By definition

often requires that the vitamin should first be concentrated, for example, into an unsaponifiable fraction or into a chromatographic fraction , but manipulative losses may detract from the advantage gained by improved spectroscopic 'quality'.

The correction procedure of Morton and Stubbs[1] incorporated in official methods now in force is used for discounting 'irrelevant' absorption The procedure makes it essential that the spectrophotometric properties of the material to be estimated shall be known with considerable accuracy , this condition is fully met in the case of all-*trans* vitamin A (see Cama, Collins and Morton[2]) and the correction procedure is indeed very successful for products containing synthetic vitamin A

Natural products, however, such as fish liver oils, contain at least three (and possibly more than three) vitamin A-active substances, namely, all-*trans* vitamin A_1, neovitamin A_1 and vitamin A_2 The latter is generally a minor component (except in some fresh-water fish liver oils), but the variability of the ratio A_1/A_2 may be as troublesome to the analyst as that of the ratio of all-*trans* to neovitamin A

Neovitamin A (the most important of several possible *cis*-isomers) and vitamin A_2 are ignored in the pharmacopœias, the revisers of which are rightly reluctant to take action which might turn out to be premature The properties of vitamin A alcohols are illustrated in Table 1.

In order to display the problem, let it be assumed that in a concentrate (for example, from cod liver oil), for every molecule of A_2 there are eight of A_1, six as all-*trans* and two as neovitamin A_1 Using *cyclo*hexane as solvent, the intensity of absorption would be

E(1%, 1 cm) at 326 mμ
All-*trans* contribution, 6/9 of 1,745 = 1,163 3
Neovitamin A_1 contribution, 2/9 of 1,615 = 358 9
Vitamin A_2 contribution, 1/9 of 1,050 = 116 7
1,638 9

The potency would be

All-*trans* contribution, 6/9 of 3 33 = 2 22 × 10^6 u /gm
Neovitamin A_1 contribution, 2/9 of 2 66 = 0 593 ,,
Vitamin A_2 contribution, 1/9 of 1 33 = 0 148 ,,
2 961

and the overall conversion factor would be

$$2\ 961 \times 10^6/1{,}638\ 9 = 1{,}807$$

The overall factor will fall as the proportion of neo-vitamin A_1 or vitamin A_2 increases, and will reach 1,687 with 30 per cent A_2, 30 per cent neo- and 40 per cent all-*trans* vitamin A_1

If correction is made for irrelevant absorption, using three points on the curve for all-*trans* vitamin A_1, the neovitamin A contribution is reduced by 20 per cent (*cyclo*hexane) and that of vitamin A_2 b 90 per cent (that is, it is almost eliminated) For mixture in which the proportions all-*trans*/neo-/A are 70/21/9, it is known that by reason of a compensation in which over-correction of neovitamin A absorption matches the lower potency (2 66 instea of 3 33 × 10^6 u /gm), the British Pharmacopœi and United States Pharmacopœia methods lead t much more trustworthy estimates of vitamin A potency than might have been expected

Three cod liver oils and two rich fish liver oil were tested at Liverpool using the British Pharmacopœia method and at Copenhagen using th chromatographic method described below Th degree of agreement was on the whole good. Th Liverpool estimates of vitamin A_2 content wer based on the colour test (antimony trichloride intensity at 693 mμ, and were higher than thos based on chromatographic separation of the vitami

The estimates of neovitamin A content using th Robeson and Baxter[8] method, which rests o different rates of adduct formation with malei anhydride, showed only moderately good agreemen with the results of chromatography

A paper on the chromatographic separation o vitamin A-active compounds in cod liver oil by F Bro-Rasmussen, W Hjarde and Olga Porotnikof from the State Vitamin Laboratory, Copenhagen was read by Mr G A J Pitt, of the University o Liverpool.

The adsorbent is dicalcium phosphate activated a described by L A Moore[9] Using the unsaponifiabl fraction from 3 gm of a cod liver oil (about 3,000 I U and a chromatographic column 50 cm long an 3 cm in diameter, the vitamin A was carried dow the column by means of light petroleum. Development of the chromatogram was completed by th use of 600 ml. of light petroleum-ether (16 1 v/v collected in 15-ml portions from the first appearanc in the eluate of material giving a blue colour wit antimony trichloride The material collected in th first 225 ml was almost entirely neovitamin A, an the all-*trans* vitamin A_1 was completely eluted in th next 225 ml , with vitamin A_2 following in the nex 150 ml The separation was clean and the spectra c 15-ml portions at the 'peak' elution of each vitami A-active component were precisely characteristic an agreed with published information

The recommended procedure is to take enough co liver oil to yield about 1,600 I U vitamin A activit and to chromatograph the unsaponifiable fraction o a 10-cm column of activated dicalcium phosphat A good deal of material responsible for irrelevan absorption can be eluted before any vitamin A this is discarded and the total vitamin A-activ material is then eluted with light petroleum-ethe The solvent is removed and the residue dissolve in absolute ethanol, and the ultra-violet absorption i measured at 310, 325 and 350 mμ. The value c E(1 %, 1 cm) at 325 mμ is taken as a measure of tot vitamin A concentration. The unsaponifiable matte is then chromatographed on a long column (60 cm > 1 5 cm). The eluents (light petroleum–ether, 400 ml 16 1 v/v, and 400 ml , 12 1 v/v) are collected i 10-ml portions and the values of E at 325 mμ ar measured Three maxima are shown when E i plotted for successive 10-ml portions, and it is eas from the graph to combine the portions containin neovitamin A_1, all-*trans* vitamin A_1 and finall vitamin A_2 The chromatography results in recover of about 90 per cent of the absorption at 325 m btained after the simple elimination of irrelevant bsorption using the short column. It is assumed hat the loss of 10 per cent is not selective and the bserved values of E at 325 mμ for the three vitamin -active components are accordingly scaled up The ll-*trans* vitamin A_1 absorption (in $E(1\ \%,\ 1\ \text{cm})$ '25 mμ) multiplied by 1,800 gives its contribution in nternational units, similarly, the neovitamin A_1 bsorption at 325 mμ is multiplied by 1,610 and that f vitamin A_2 by 1,060 (solvent is ethanol)

The British Pharmacopœia method is simple and ortunately gives trustworthy results for the total itamin A_1 activity The vitamin A_2 contribution ay be determined separately

J Walter Lord and Miss P M Bradley submitted method for the spectrophotometric estimation of itamin A in margarine The amount of vitamin A c 30 I.U./gm) is not great and the unsaponifiable raction shows a good deal of irrelevant absorption erived from the constituents of the fat or from dded carotenoids or dyes Boldingh and Drost[10] escribed an effective procedure for obtaining from argarine a fraction practically free from irrelevant ltra-violet absorption, and the method has received fficial recognition[11] It depends on chromatography sing two specially activated adsorbents in tandem olumns, and although simplifications of the method ave been suggested (for example, by Rosner and an[12]) it is still necessary for the analyst to undertake two preparations of specially activated alumina

The modified method of Lord and Bradley is more onvenient It is based on a simple chromatography sing bone meal, an adsorbent advocated by Mann[13] nd used by Goodwin and Morton[14] for separating arotene and vitamin A unsaponifiable extracts from argarine Commercial defatted bone meal is suitble if it passes an 80-line sieve but is retained by a 70-line sieve These limits are not critical, but articles of this size allow a reasonable rate of flow f solution and also permit absorbing impurities to e separated from vitamin A

The unsaponifiable fraction from 10 gm of mararine is dissolved in petrol (boiling point, 80–100°) nd transferred to a column of bone meal (9 in × in) already full of petrol The yellow dye or the dded carotene can be washed through the column y means of petrol (slight air-pressure is useful) hen the eluate is no longer coloured, the solvent is hanged to petrol containing ether (16 per cent v/v) nd the eluate is then collected in 5-ml portions he tubes containing vitamin A are identified by sing the Carr–Price test on very small portions of luate Aliquots are withdrawn and united for pectrophotometric measurements at 315, 325 and 35 mμ

Vitamin A alcohol could be recovered from the olumn without loss or spectroscopic impairment hen it was added to the unsaponifiable fraction rom unvitaminized margarine, the average 'recovery' as 108 per cent, in close agreement with experience f the official method (compare Morgareidge[15]) The igh 'recovery' is due to the presence of material xhibiting irrelevant absorption The reading at 15 mμ is always somewhat greater than that of 35 mμ, but the irrelevant absorption at 335 mμ is ery small The difference between readings at 315 mμ nd 335 mμ gives a good approximation to the irrelevant absorption at 325 mμ When this correction is pplied, 'recovery' is nearer 100 per cent Comparison f the results of the new method and the official ethod showed excellent agreement, and many workers may find the simplicity of the bone meal method attractive

A brisk discussion followed The possibility that the neovitamin A_1/all-*trans* ratio might be altered by saponification was mentioned The constancy of bone meal was also queried, however, this adsorbent is reproducible and can be used several times.

NATIONAL RESEARCH COUNCIL OF CANADA

ANNUAL REPORT FOR 1953–54

THE thirty-seventh annual report of the National Research Council of Canada* covers the year ended March 1954, and, following the pattern of the last report, includes, besides the president's report and the financial statement, the annual report of Canadian Patents and Development, Ltd, for the year ended March 31, 1954 Pilot-plant operations on the Cambron process for the direct oxidation of ethylene were discontinued, but the pilot plant is being maintained in a standby condition, and the Applied Chemistry Division of the National Research Council has carried out further research on reactors for the Company The Company has also established a Development and Promotion Section to encourage contact with industry and the use of inventions controlled by the Company

The president's report records that during 1953 the National Research Council provided two million dollars in 420 awards and 230 scholarships and fellowships for fundamental research in the universities Its scientific staff numbered 535, with 679 non-professional technical personnel and 741 others employed in services, maintenance and administration as well as some eighty post-doctorate Fellows Technical inquiries from Canadian industries are now running at the rate of eight thousand a year, and already some eighteen hundred science graduates have gained advanced training in research by the Council's extra-mural support of fundamental research New buildings for the Divisions of Applied Chemistry, Building Research and Radio and Electrical Engineering were completed during the year, and additions made to the thermodynamics building

In the Division of Applied Biology, the industrial possibilities of the improved citric acid fermentation process as an outlet for Canadian sugar-beet molasses are now being tested in the pilot plant. Research on dairy products has indicated the protective action of dissolved lactose on milk proteins during frozen storage, while electron microscope studies, in collaboration with the Department of Agriculture, have established the way in which a virus attacks bacterial disease of crop plants and the size and shape of the virus. The role of lipoxidase, an enzyme occurring in plant tissues, in the oxidation of fats is being evaluated, and radioactive tracer techniques have shown that in detached sugar-beet leaves a ten-second photosynthetic period yields significant amounts of such complex molecules as cellulose, as well as simple sugars and amino-acids

---

* Thirty-seventh Annual Report of the National Research Council of Canada, 1953–54, including the Annual Report of Canadian Patents and Development, Limited (N R C No 3286) Pp 50 (Ottawa National Research Council, 1954)

In the Prairie Regional Laboratory, Saskatoon, the major effort is being concentrated on production from agricultural wastes and surpluses of such substances as enzymes, antibiotics, vitamins for feed supplementation, and other compounds obtainable only by biological synthesis. Current investigations include studies on the physiology and biochemistry of living plants, the mechanism of fermentation processes using sugar or carbohydrate nutrients, and the chemistry of such plant materials as starches, sugars, cellulose, lignin, proteins, fats and oils The process for separating prime starch and vital gluten from wheat flour has been improved, and trials of the new fluidized-bed dryer indicate that wheat can be dried at air temperatures greatly in excess of 180° F. (82 2° C.) without damage or loss in baking quality. The Maritime Regional Laboratory, Halifax, has been concerned largely with fundamental and applied aspects of the utilization of seaweed. Rockweed appears to be a less suitable source of alginate than kelp The distribution of amino-acids in the proteins of several species of seaweed has been determined, the chemical structure of fucoidin from rockweed clarified by isolation of a new crystalline disaccharide, maritol, and carrageenin from Irish moss fractionated into a polymer which appears to be responsible for the high viscosity of the sol fraction and another governing gel strength.

In the Division of Pure Chemistry, the red pigment uroporphyrin I has been synthesized and its structure confirmed, while it has also been shown that the two alkaloids, hordenine and gramine, generated in sprouting barley, are formed from amino-acids, the first from tyrosine, and the second from tryptophan Further information about the internal structure of the hydrogen peroxide molecule has been obtained in low-temperature measurements by the Low Temperature Colorimetry Section in collaboration with workers at Laval University, and the thermodynamic functions of hydrogen peroxide gas have been calculated up to 1,200° C A thermal diffusion column built by the Section on Physical Properties of Liquids and Gases for the separation of krypton isotopes gave a krypton-84 containing only 2 4 per cent of krypton-86

In the Division of Applied Chemistry, besides work on the catalytic oxidation of ethylene, much effort has been spent on the evaluation of silver catalysts for the process In collaboration with the Canadian Research Institute of Launderers and Cleaners, a study of the sorption of surface-active agents by textile fibres was completed, and studies were being made of the factors affecting the soiling characteristics of textile fibres, of the microbiological and ultra-violet breakdown of cellulosic fibres, and of methods of measuring damage in the newer synthetic fibres The study of inhibitors for the corrosion of metals in water and in glycol an freeze systems continued, as well as developme work on the production of high-purity single cryst of germanium. A study of the decomposition of t polymerizing and blowing agent 'Porophor *N*' w completed, and work was started on the oxidation polyvinyl alcohol by Fenton's reagent

In the Division of Physics a universal detector f atomic and molecular beams has been develop which has already been used in the study of silv gold and boron. The presence of free aldehy radicals when acetaldehyde, formaldehyde or glyox is irradiated by ultra-violet light has now been esta lished, and the Spectroscopy Laboratory has al resolved the Raman spectra of benzene vapour a obtained precise values for the geometrical dime sions of the benzene molecule Important informati about the nature of the primary cosmic radiati and on nuclear reactions caused by cosmic rays h been obtained from a microscopic study of plat exposed in balloons at altitudes of more th 100,000 ft , while, in a theoretical evaluation of oth experimental data on the upper atmosphere, t variation of the dissociation of molecular oxygen in atoms with height has been derived and the variati of the electron concentration in the *E*-layer calculate Apparatus is being set up to study the electrical a other properties of metals under pressures up 10,000 atmospheres In the Applied Physics Branc studies by the Acoustics Laboratory indicate th ultrasonics are ineffective as repellents for duc and ring-billed gulls An improved ear defender h been developed to the prototype stage Experimen were in progress on the determination of the gravi constant by direct observations on a falling bo using modern optical and electronic development A new technique has been developed which increas the precision and convenience of interferometry measuring length, and the extension of existi ground control points by mathematical computati from measurements on air photographs was al being examined in co-operation with the Universi of Toronto. A set of carbon-filament lamps f photometric standards has been calibrated using small refractory tube immersed in molten platinun and the amount of radiation in the beam emitted cobalt beam therapy units was being measured the Radiology Laboratory A photographic 'came calibrator' has been constructed for air cameras a put into use.

The dedication on October 23, 1953, of the ne Building Research Centre, which is believed to the first building of its kind designed to serve t general needs of building research, was the cu mination of the first three-day Conference on Buildi Research to be held in Canada. The new buildi does not include accommodation for the Division work on fire research, which has progressed steadi during the year, in relation both to fire losses and civil defence. The Division continues to opera Canada's only sound chamber for acoustical researc in relation to buildings, while important results o the reflective insulation of walls in cold weather hav been obtained by the Division in the Prairie Region Laboratory at Saskatoon Work on the revision of th national building code continued, and the Divisio broadened its work in the field of technical housin research.

The Division of Mechanical Engineering continue its investigations of means of protecting aircraft an engines against de-icing, while in aerodynamics th

SESSION 1954–1955

Course of Seven Evening Lectures

on

PRECISION TIMEKEEPING

by lecturers from The Royal Observatory, National Physical Laboratory and Post Office Engineering Dept.

FRIDAY EVENINGS: 6.30–8.30 p.m.
commencing 21st JANUARY, 1955

The course has been planned as a review of modern methods of precise timekeeping and standards of time and frequency for horologists, physicists and engineers

•

The fee for the course is £2 2s Students may enrol by post or by personal attendance at the College up to 17th January, 1955 The Northampton Polytechnic, in which the College is accommodated, is a few minutes walk from the Angel Underground Station (N Line)

Automatic Feedback Control System Synthesis

JOHN TRUXALL

Associate Professor of Electrical Engineering, Polytechnic Institute of Brooklyn, Associate Professor of Electrical Engineering, Purdue University

This work is a complete up-to-date presentation of the methods useful in the design of feedback systems The highly developed theories of the design and synthesis of linear systems are covered in detail, and it concludes with analysis and design of non-linear systems

A solid theoretical foundation is placed under the elementary design techniques The Laplace transformation is used in connection with design, in contrast to the conventional approach

Synthesis of feedback systems in terms of polezero configurations is considered in detail with an extended discussion of the root-locus method and a full development of the concept of initiating design in terms of the poles and zeros of the closed-loop system function

Engineering Cybernetics

H S TSIEN

Goddard Professor of Engineering, California Institute of Technology

FLORENCE GUGGENHEIM

Jet Propulsion Centre, California Institute of Technology

This work aims to establish engineering cybernetics as a new branch of engineering science Its purpose is to study those parts of the broad science of cybernetics which have direct engineering applications in designing controlled or guided systems It includes topics normally treated in books on servomechanisms, but is predominated by theoretical analysis

About two-thirds of the material treats new subjects, many of which have never before appeared in book form

This is a truly significant text and reference book developed for a course on the theory of stability and control It should also serve as an introductory text to control engineering for physical and mathematical scientists who may wish to do research in the field

MACMILLAN BOOKS

Intermediate Chemistry

Sixth Edition

T. M. LOWRY, C.B.E., M.A., D.Sc., F.R.S.

Late Professor of Chemistry in the University of Cambridge

A. C. CAVELL, M.A., B.Sc.

Senior Science Master at Uppingham School

The main intention of this new edition of *Intermediate Chemistry* has been the re-writing of the Organic Section. Several changes have been made to the Inorganic Section, and there have also been a number of other alterations to and extensions of the work, which is designed to provide a complete text-book of chemistry for Intermediate and General Certificate (Advanced and Scholarship) Examinations. 18*s.*

Semimicro Qualitative Analysis

A Course in Applied Chemical Equilibrium

EDWIN O. WIIG, Ph.D., WILLARD R. LINE, Ph.D., and JOHN F. FLAGG, Ph.D.

This revision of *Semimicro Qualitative Analysis*, while retaining the experimental procedures and much of the form of the earlier text, has been almost completely rewritten. The theoretical section has been considerably expanded, and a large number of problems of varying difficulty (with the answers to many of them) have been added. The sections on special procedures for ferro- and high-aluminium alloys have been modified on the basis of student experience. 25*s*

Functions of a Complex Variable

THOMAS M. MACROBERT, M.A., D.Sc.

Professor of Mathematics in the University of Glasgow

This book is designed for students who, having acquired a good working knowledge of the calculus, desire to become acquainted with the theory of functions of a complex variable, and with the principal applications of that theory. In order to avoid making the subject too difficult for beginners, the author has abstained from the use of strictly arithmetical methods. *Fourth Edition* 20*s*

From Small Beginnings

E. N. da C. ANDRADE, D.Sc., Ph.D., LL.D., F.R.S.

This little book is based on a series of six television talks given by Professor Andrade, and is the result of letters which were occasioned by them. In it he deals with some of the experiments and thoughts behind a few simple scientific discoveries which have led to such advanced developments as the radio, the aeroplane, the motor car, and the electric lamp. 3*s.* 6*d.*

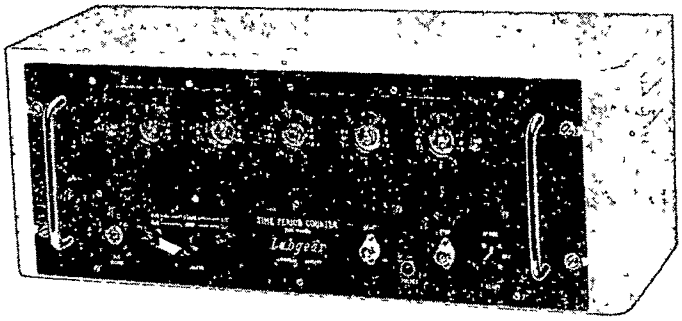
Precision Timing!

TIME-PERIOD COUNTER

D.4108



An inexpensive crystal controlled Counter-Chronograph which operates in the range 10 to 10^{-4} seconds for the accurate measurement of the time interval between two events.

An extremely flexible triggering arrangement permits the counter to be operated from

(a) Two consecutive pulses, having a common origin
(b) Two pulses derived from independent sources
(c) A mechanical contact sequence involving s/c Start—o/c Stop, i.e. closed during period under observation, or alternatively,
(d) o/c Start—s/c Stop, i.e. open during the period under observation.

Quartz crystal frequency 10 Kc/s—accuracy 0.02% over a temperature range of —10°C to +70°C.

The normal time-count capacity of 10 seconds may be extended to ten thousand seconds by the addition of Dekatron Register D.4019/V, or to one million seconds by the addition of Dekatron Counter D.4104/B.

Supplied complete with dust cover for standard G.P.O. rack mounting.

Price in U.K. £100

Bench mounting cabinet available at extra cost

Rapid centrifugal preparation

with the Spinco Model L

ULTRACENTRIFUGE

- VACUUM
- 162 ml – 40,000 rpm
- REFRIGERATED

FULLY-AUTOMATIC features make the Spinco Model L Preparative Ultracentrifuge operationally self-supervising Simple speed- and time-controls are preset by operator and electronic unit brings rotor to speed, times run, and decelerates with smoothly operating automatic brake

Various sizes and types of interchangeable rotors mount in operating chamber with instantaneous coupling Time between runs, using pre-loaded rotors, is less than a minute Speed and vacuum are established almost simultaneously Acceleration time for the 40,000-rpm rotor is only four minutes

SAFETY FEATURES include automatic overspeed cutout, interlocks to prevent running at high speeds without vacuum in chamber and prevent breaking vacuum or opening chamber while running at high speeds Rotor chamber is encased in thick double steel guard

Unit is self-contained, of worktable height, and requires only electric connection for installation Spinco electric drive and gearing system are of types proved in more than 100,000 hours of actual field operation Self-balancing feature eliminates weighing of loaded tubes Controllable refrigeration holds rotors and contents at any temperature down to -5 C

In operation, the Model L applies forces up to 144,000 times gravity on 162 ml of material at a maximum speed of 40,000 rpm Individual rotor tubes have sealing caps—are available in plastic or metal Rotors provide second vacuum seal in quickly-detachable cover with integral lifting device Wide selection of rotors is available with largest holding 1700 ml—limited to 20,000 rpm

Correct Diagnosis depends on

CONSTANT VOLTAGE

Medical science to-day relies to an increasing degree on electronic instruments for the diagnosis of disease The accuracy of the results obtained is of vital importance and is dependent on the reliability of the electricity supply available ADVANCE Constant Voltage Transformers provide the means for regulating the inevitable fluctuating mains voltages which both shorten the life and impair the efficiency of such equipment They are used in many hospitals and medical laboratories for this very purpose A wide range of models is available with ratings from 4 watts to 6 kilowatts All these models provide a stabilized output voltage to within ±1 per cent for mains variations of up to ±15 per cent

Full details of Advance Constant Voltage Devices are given in folder N/28 gladly sent on request.

Purer than the driven snow !

ASK T. B. FORD for the answer to any filtration problem, and a perfectly pure and lucid filtrate is yours. Ford's are experts in filtration. They make filtration media for every type of filter—and the standard of efficiency is unsurpassed.

From Ford's, you can obtain filtration media so efficient that they can be used to remove contaminating bacteria and moulds, thus sterilizing the liquids passed through them. This thorough filtration is achieved by the careful, precise admixture of asbestos fibres and cellulose, providing a mat that retains a high degree of porosity and permits a high rate of flow. Ford's Sterimats and Claraid not only filter but adsorb any micro-organisms that would spoil an otherwise stable, immaculate, crystal-clear filtrate.

Twenty years of continuous laboratory research and experiment have made T. B. Ford Ltd *the* authority on every aspect of filtration media. And they make the best in the world.

This laboratory service is filtration NEWS!

Ford's provide a laboratory service, staffed by a team of experts, which is available to all manufacturers, free of charge. Some manufacturers, with their own fully-equipped laboratories, simply want Ford's to check and confirm their own research findings. Others call upon Ford's to solve some particular problem in their filtration process, whether directly concerned with the media itself or not. Whatever the problem, Ford's will gladly undertake the necessary laboratory research. Write to T. B. Ford Ltd., Laboratory Service, 101 High Holborn, London, W.C.1.

DIRECT READING Spectrochemical Analysis

●

Up to Ten Elements can be quickly and accurately analysed with the Direct Reading Attachment to the Hilger Medium Quartz Spectrograph

The plateholder of the spectrograph is replaced by a unit which will accommodate eleven photomultipliers and slits adjusted accurately on appropriate spectral lines A complete analysis takes under three minutes

Extensive tests have shown that sensitivity is high and reproducibility often better than is obtained with photographic methods

A new design of arc and spark stand ensures that samples are aligned rapidly and precisely Either pencil electrodes or flat specimens can be examined with equal ease

Provision is made for compensating for variations of temperature

The attachment has been used in determining the composition of aluminium, lead, magnesium and other alloys. Results of tests carried out in the Hilger laboratories will be forwarded on request.

Please write for Hilger catalogue CH 383 (*N* 1) *for description of the instrument and CH* 392 (*N* 1) *for applications and results*

emphasis has shifted towards the transonic and supersonic speed-range In hydrodynamics the St Lawrence Seaway project became a major interest, and a 1/30 scale model of one of the navigation locks was being used for determining the effect of the spacing of the filling ports and valve-opening schedules upon the rate of filling of the lock and upon variations in the water surface Gas turbines absorbed the major effort in thermodynamics, and a system of thrust boosting for aircraft jet engines by exhaust reheat was being developed in which most of the additional fuel is injected before the turbine The influence of fuel composition, antioxidants, drum materials and other factors on the rate of deterioration of fuels in storage was being investigated, and a theoretical analysis of the stiffness and optimum weight-stiffness of tubes with inclined ribs showed that true optimum weight-bending stiffness configurations exist in the conventional wing range of aircraft structures, but that for torsion the optimum condition is beyond applicable limits

Much of the work of the Radio and Electrical Engineering Division has continued to be on defence projects, but a microwave position-fixing system for vessels engaged in offshore survey operations has been developed and constructed, as well as a microwave link for remote control of isolated fog-alarm stations, and a wired-television link with a remotely controlled camera mounted in a submersible cylinder which permits surface operators to study aquatic flora and fauna, bottom details, wharf pilings, hulls, etc , to depths of a hundred feet A new merchant-marine radar set with improved performance in both short-range definition and long-range detection has also been developed, while studies of semiconductors have led to an understanding of the operation of a crystal rectifier at high voltage An improved antenna has been developed for use with domestic television receivers as well as a highly accurate frequency-measuring attachment for radio receivers and also a combined electro-phono-cardiograph which presents simultaneously on the screen of a cathode-ray oscillograph the wave forms of the electrical impulses from the heart together with those of the sounds due to heart motion A new type of mass spectrometer, the 'omegatron', for determining the constituents of gas mixtures, has been designed and built.

Most of the 136 grants-in-aid made by the Division of Medical Research were in the basic medical sciences, about two-thirds being for a continuation of previous studies Some grants for experimental studies in pathology and surgery indicate an interest in the cause and nature of disease and in physical methods of treatment

---

EXPERIMENTAL INVESTIGATION OF LEAF FORMATION, SYMMETRY AND ORIENTATION IN FERNS

By Prof C W. WARDLAW
Department of Cryptogamic Botany, University of Manchester

INVESTIGATIONS of the inception and development of leaf primordia in *Dryopteris austriaca* have yielded the following information. (Primordia are referred to as P_1, P_2, P_3, etc , P_1 being the youngest visible primordium , I_1 indicates the site of the next primordium to be formed and I_2 the next after that The tetrahedral cell at the tip or summit of the shoot and its recently formed segments are referred to as the 'apical cell group')

(i) Leaf primordia are always formed on an apical meristem

(ii) A leaf primordium typically originates near the base of the apical cone It consists of a circular to elliptical group of the distinctive, superficial prism-shaped cells of the apical meristem, which grows out, forming a low mound of tissue , the small-celled tissue within is also in a state of active division

(iii) A young primordium, situated between and above two older ones, occupies only a small part of the free surface of the apical cone.

(iv) On further development, an approximately central, superficial cell of the primordium now becomes much enlarged During this process, this 'leaf apical cell' acquires its characteristic 'two-sided' shape, its orientation being such that the segments produced by its division lie in the tangential plane. These give rise to the marginal meristems from which the tissues of the primordium are formed.

(v) The alignment of the leaf apical cell and of its partition walls at cell division is thus at right-angles to the principal direction of growth in the subtending apical cone, that is, the tangential direction , and it may well be that the shape and disposition of the leaf apical cell are directly attributable to the relatively large tangential component of growth in the leaf site. Once the two-sided apical cell has been established, the foliar nature of the primordium is irreversibly determined

(vi) In relation to the position in which a leaf primordium originates, that is, on the side of a cone, growth on its abaxial side is more rapid than on its adaxial side , and this difference soon becomes accentuated as the primordium passes into the actively growing and rapidly widening subapical region of the shoot (Fig 1). It thus appears that the

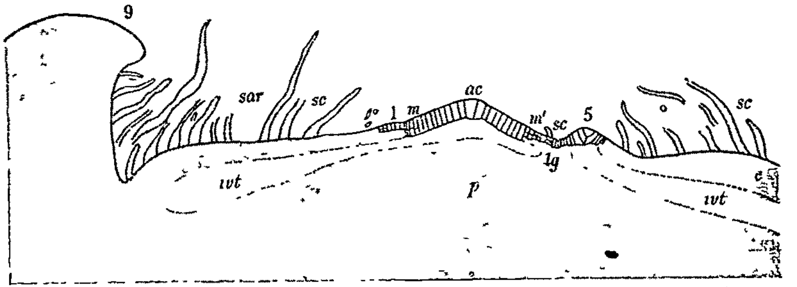

Fig 1 *Dryopteris austriaca*, the apical cone as seen in median longitudinal section, traversing the youngest visible primordium (1) and older ones (5, 9) The apical cell, *ac*, and the distinctive prism-shaped cells of the apical meristem *m–m′* are shown *sc*, scale , *c*, cortex , *p*, pith , *ivt*, incipient vascular tissue , *lg*, leaf-gap , *sar*, sub-apical region (Semi-diagrammatic × 30)

orientation, dorsiventral symmetry and shape of a developing primordium may be referred to the growth activity of the region of the shoot apex in which it originates and to the disposition and activity of its own apical and marginal meristems

(vii) While a primordium still forms part of the apical cone, its growth is relatively slow, but once it is in the subapical region, its growth and morphological development are rapid The sooner a primordium comes to occupy a subapical position, that is, as a result of the growth of the shoot apex, the more rapid will be its enlargement and morphological elaboration Thus, a P_3 primordium on a small apex of low phyllotaxis is larger and more elaborate than a P_3 on a large apex of high phyllotaxis

(viii) The actual inception of leaf primordia is an obscure and complex phenomenon In ferns, the indications are that a primordium is formed at a growth centre, that is, a locus of special metabolism The position of this centre is apparently controlled by the apical cell group at the summit of the shoot and by the two adjacent primordia of the top whorl The growth centre consists of a circular group of seven to nine meristem cells in which we may suppose there is an accumulation of the substances that determine the outgrowth of a lateral organ

On the basis of experimental observations, I have already attempted[1] to relate leaf symmetry and orientation in ferns to the position in which the primordium originates, and to possible inhibitive effects proceeding basipetally from the apical cell group Thus it was shown that if the I_1 position is isolated from the upper part of the apical meristem by a deep tangential incision, a bud, and not a leaf, is formed In general terms it was thought that, as a result of this operation, inhibitive effects from the apical cell group would be precluded, and a levelling up of the growth-rates on the adaxial and abaxial sides of the primordium might take place If so, the development of a radially symmetrical organ, that is, a shoot bud, might be expected Cutter[2] has since shown that if P_1 and P_2 are similarly isolated before the characteristic two-sided initial cell has been formed, they, too, can be transformed into buds, and Wardlaw and Cutter[3] have shown that the prevascular tissue, which immediately underlies the prism-shaped cells of the meristem, is important in these several morphogenetic developments

In some recent experiments an attempt has been made to ascertain whether the dorsiventral symmetry and orientation of leaf primordia can be attributed (*a*) to a specific localized effect, on the adaxial side of the primordium, of an inhibiting substance proceeding from the apical cell group, or (*b*) to the regulated growth which is characteristic of the intact shoot apex as a whole. In relation to (*b*), it may be noted that there is a steady acceleration in the rate of growth from the apex to the base of the apical cone, and a rapid acceleration of growth in the region of transition from the base of the cone to the sub-apical region (Fig 1) Primordia originate near the base of the cone and are soon affected by this active region of transition Wide and deep tangential incisions above P_1 and I_1, whereby the formation of buds can be induced, would evidently preclude (*a*) and cause serious disturbances to (*b*) Here it is relevant to note that when bud formation is induced in a leaf site, for example, at I_1, or by the transformation of a leaf primordium, for example, P_1, the bud not only quickly develops a large apical meristem but also shows strong growth on its adaxial side.

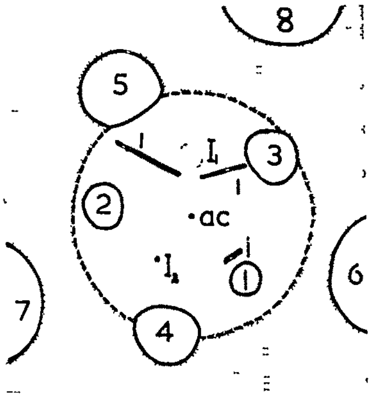

Fig 2 *Dryopteris austriaca* Apex as seen from above, showing leaf primordia 1–8 and the positions of I_1, the next primordium to be formed, I_2, the next after I_1, and the apical cell *ac* A small deep incision, *i*, has been made on the adaxial side of P_1 Two wide and deep tangential incisions, *i*, *i*, have been made above I_1 so as to leave a 'bridge' of intact tissue between the primordium site and the apical cell The sub-apical region is stippled

Of a considerable and varied series of new surgical experiments which have now been carried out, the two most directly relevant to the problems of leaf and bud formation are illustrated diagrammatically in Fig. 2 In one series, small deep tangential incisions, severing the incipient vascular tissue, were made immediately above I_1, I_2, P_1 and P_2 If dorsiventrality in a primordium is due to a limitation of the growth-rate on its adaxial side, that is, as a result of the basipetal movement of a growth-regulating substance from the apical cell group, some bud formation might be expected in this experiment In the other series, two deep and extensive tangential incisions were made just above a primordium (or primordium site), so as to leave a 'bridge' of intact tissue between it and the apical cell group If dorsiventrality is mainly due to a localized (adaxial) inhibitional effect proceeding from the apical cell group, then leaves should still be formed, but if it is a result of the regulated growth of the apex as a whole (or of the sector in which the primordium is situated), then, in relation to the extensive restriction of both the acropetal and basipetal movement of metabolic substances by the tangential incisions, and the consequential radical disturbance of the normal distribution of growth in the apical cone, some bud formation might well be expected.

The results of these two experiments are set out in Tables 1 and 2, the records relating to specimens in which the apical cell group remained intact and quite undamaged (These experiments are of some delicacy and not easy to perform successfully)

The evidence from the first set of experiments (Table 1) is conclusive small adaxial incisions have in no instance resulted in bud formation It thus appears that the dorsiventrality of leaves cannot be attributed to the localized action of a growth-regulating substance on the developing primordium

The evidence from the second series, though less conclusive, is none the less important In at least some apices (actually 25 per cent of all primordia and 40 per cent of I_1's), bud formation can be induced when the apical cell is undamaged and when intact tissue extends between it and the primordium (Fig 3) In those apices in which buds were formed, the experimental region was marked by very con-

Note Where the 'bridge' had been eliminated, that is, by the two incisions joining up, or where the shoot apex had been damaged, even very slightly, buds were usually formed Where the 'bridge' was wide, leaves were usually obtained, though occasionally a bud was formed

spicuous growth activity and the buds were of large size (Fig 3). Late-season apices, which were relatively inactive, typically yielded leaves

Where buds were obtained, as in Fig 3, microtome sections showed that the bud was in vascular continuity with the parent shoot in the region of the 'bridge'

In the light of these experimental results, to what factors and relationships may the organization of the fern apex and its orderly morphogenetic activity be attributed?

There is considerable support for the view that the apical cell group is a region of special metabolism, as is also each growth centre which may become a leaf, or, if subjected to experimental treatment, a bud. Products of the metabolism of the apical cell group, moving basipetally by way of the prevascular tissue, may exercise a regulative effect on the growth of the apical and sub-apical regions Thus, in the upper part of the apex, where the concentration of the growth-regulating substance will be high, the rate of growth of the meristem cells may be kept low, but lower down, and in the region of transition to the sub-apical region, where the concentration of the growth-regulating substance will be much lower, growth may be promoted. This hypothetical substance, which might be an auxin or hormone, or a precursor of one or other of these, is likely to be essential in some way to protein synthesis, as Skoog[4] has recently suggested An important feature of this conception is that the substance will produce its organizing and morphogenetic effects by the way it affects the growth of individual cells, each of which will react in a characteristic way according to its physiological state, rather than by its action on primordia as such

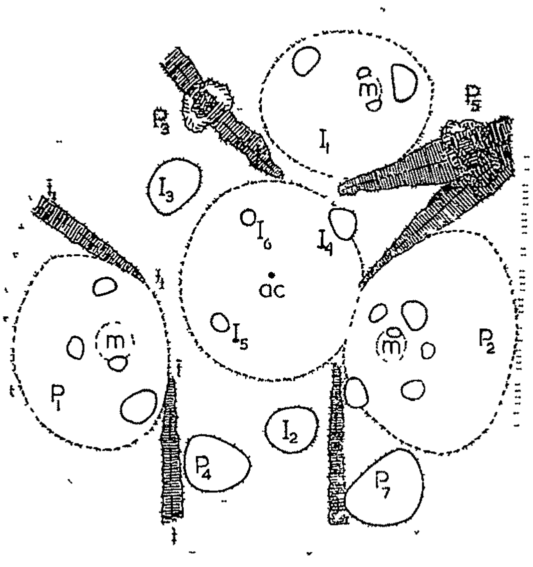

Fig 3 *Dryopteris austriaca* Apex, as seen from above, showing the large buds which have been induced in the I_1, P_1 and P_2 positions when these positions were partially isolated from the shoot apical cell by two wide tangential incisions In each instance a 'bridge' of intact tissue was present on the adaxial side of the primordium *ac*, position of the apical cell of the main apex P_1–P_7, primordia present at the beginning of the experiment, P_1 and P_2 having been transformed into large buds The locus of I_1 has also developed into a large bud ii–i_1i_1, tangential incisions I_2–I_6, new leaf primordia formed during the course of the experiment *m*, apical meristem of induced buds The broken lines indicate approximately the bases of the main apex and of the buds (Diagrammatic camera lucida tracing, × 15)

An alternative view might take the form that the apical cell group is not a locus of special metabolism, the organization of the apex being due to competition among its constituent cells for the nutrients involved in growth As these nutrients move acropetally from the older regions below, with differential utilization of the several substances at different levels *en route*, the supply will diminish progressively and change qualitatively as the shoot tip is approached

The most satisfying explanation, however, probably lies in a combination of the two views Thus destruction or isolation of the shoot tip would simultaneously remove both its regulative and competitive activities In the 'bridge' experiment described above, the two wide tangential cuts go a long way towards isolating the shoot tip, and, as we have seen, marked growth activity may be induced on the adaxial side of primordia and buds may be formed On the other hand, as even a cursory inspection will show, a small incision above a primordium will do little to modify the normal movement of metabolites As rapid wound-healing, with formation of parenchyma and an outgrowth of scales, takes place at the injured tip and in proximity to incisions, it is evident that both the quantity and quality of the nutrients being drawn upwards are different from those normally utilized in the growth of meristem cells Scale and parenchyma formation, indeed, are characteristic of the normal growth developments on the abaxial side of actively developing primordia. Furthermore, in apices with a damaged tip, young primordia, already determined as leaves, may be observed facing and curving outwards instead of inwards, in relation to the high rate of growth on the adaxial side

In conclusion, it may be noted that in the ferns the apical cell is the focal point in the distal meristem and is essential for the continuing growth of the shoot. It may also be regarded as the ultimate determiner of the orientation and symmetry of leaf primordia. But such effects are apparently not produced by its direct action but are mediated through the organization and physiological activity of the apex as a whole

A NEW ABSOLUTE HYGROMETER OF HIGH ACCURACY

By DR. R G WYLIE

Division of Physics, National Standards Laboratory, Commonwealth Scientific and Industrial Research . Organization, Sydney

THE history of hygrometry, especially during the past few decades, has been characterized by a continual searching for new methods which do not suffer from the shortcomings of inaccuracy, slow response or general inconvenience encountered with the classical methods Probably the most important developments which have resulted are the electrolytic method of Dunmore[1] and the 'Dewcel' described by Hickes[2], both of which have been successfully applied in particular fields These methods involve the construction of relatively complex and expensive sensitive elements

Dunmore's elements, and somewhat similar types developed since, suffer from the disadvantage that their humidity – resistance relationship is empirical and subject to change with time and especially with exposure to extreme conditions The 'Dewcel' method is limited in accuracy by the fact that the electrode wires occupy an appreciable fraction of the surface area of an element, and by changes which occur in the electrolytic medium The error of a 'Dewcel' can be determined only by comparison with an independent hygrometer

No convenient method of hygrometry has yet been reported which can approach the accuracy of the dew-point method

The dew-point method itself suffers from a number of disadvantages, notably that the visual instruments are slow and tedious to use and that the presence of contamination on the dew-condensing surface can give rise to unsuspected errors On account of the way in which condensation and evaporation occur, and because of the operator's desire to achieve the best accuracy, the tendency, both with visual instruments and with automatic instruments in which the condensing surface is examined by photoelectric or equivalent means, is to work with the smallest possible quantity of dew The effects of contamination will then be greatest In fact, during condensation on a polished surface, the amount of light scattered by the deposit increases only during the earliest stages, associated, in most cases, with the dissolving of minute quantities of soluble matter and the dilution of the consequent solution Only an instrument in which equilibrium can be established between pure phases can yield results which are independent of the mechanism of the phase change and hence which are accurately reproducible

The method to be described here is absolute in the same sense as the dew-point method, and is more accurate and more amenable to instrumentation.

The principle is simple and is derived from the fact that water vapour is taken up by the surface of a water-soluble crystal if the water-vapour pressure is greater than the vapour pressure of a saturated solution of the crystalline substance at the temperature of the crystal surface This gives rise to a layer of saturated solution on the surface of the crystal, and for any soluble crystal surrounded by moist gas of constant composition a critical temperature exists at which the surface layer is in equilibrium with its surroundings If the crystal is ionic, the presence of this layer, as well as changes in its thickness, can readily be detected by electrica methods. By raising or lowering the temperature of the system the critical temperature can be determined with great precision, since the electrical resistance of the layer, which is too thin to flow, will remain constant at that temperature The partial pressure of the water vapour in the gas surrounding the crystal can then be deduced from a knowledge of the vapour pressure of the saturated solution of the salt as a function of temperature

If a temperature which is slightly higher than the critical value is maintained, the electrical resistance between suitable electrodes making contact with the crystal surface will increase steadily until a very high value is reached which is related to the adsorption of water at the surface If a temperature which is slightly lower than the critical value is maintained, the resistance will decrease steadily until the ionic substance is excessively dissolved If the surface of a pure ionic crystal is clean, the actual value of the electrical resistance, the constancy of which indicates that the critical temperature has been established, may be chosen arbitrarily within a very wide range For example, using a crystal of potassium chloride of cubic form, it has been found that for resistances measured between opposite faces of the crystal, of less than 0 05 to more than 5 megohms, the equilibrium temperature is constant within the accuracy of the best measurements made, namely, ± 0 01 deg C

Laboratory Evaluation of the Method

The practicability and accuracy of the method were first demonstrated by the following simple experiment Atmospheric air was brought into water-vapour equilibrium with saturated sodium thiosulphate ('hypo') solution by bubbling it slowly through a tube containing a slightly undersaturated solution of 'hypo' and then passing it through a tower containing moist 'hypo' crystals , this was done in a stirred Dewar vessel at room temperature

The air was then brought to the temperature of the stirred water in a second Dewar vessel by passing it through a glass coil immersed in the water Thence it passed through a glass tube, also immersed in the second vessel, in which an approximately cubic single crystal of 'hypo' was held between two parallel graphite plates each approximately 2 mm square The electrical conductance between the crystal supports was measured using a direct-reading electronic unit of simple design which passed a 50 c /s alternating current of about 5 μamp between the electrodes when the resistance was about 0 5 megohm The sensitivity was such that a resistance change of 1 per cent was easily detected

By adding a few drops of either warm or cool water to the Dewar vessel containing the crystal unit, the temperatures in the flasks, which were measured with mercury-in-glass thermometers, could be equalized at approximately room temperature or caused to differ slightly either way By interchanging the thermometers during an experiment, their separate calibration was rendered unnecessary

Using the criterion that the resistance should be constant at some value in the range of 0 5–2 megohms it was found that the temperatures could be equalized repeatedly as accurately as the thermometers could be read Since the thermometers were similar and were divided to 0 05 deg C, temperature equality to ± 0 01 deg was therefore proved, thus establishing that the principle could serve as a basis for precise hygrometry

Practical Form of the Hygrometer

A satisfactory form of the hygrometer is a small isothermal metal enclosure, about an inch long and an inch in diameter, in which a suitable ionic crystal is mounted on two chemically inert electrodes. The gas, the humidity of which is to be measured, is allowed to fill the enclosed space, which is cooled or heated as the case may require until the critical temperature is reached. If the gas is to be passed continuously through the enclosure, as will often be the case, it must be brought to the temperature of the enveloping metal before it is admitted This may be achieved by first passing the gas through channels cut in the piece of metal or through an attached coil of metal tube

The enclosure may be cooled by the passage of a refrigerant through appropriate channels Carbon dioxide expanded at a small needle valve from cylinder pressure to atmospheric pressure may be used as a clean and easily regulated refrigerant Heat may be provided electrically using a resistance winding of insulated wire wound directly on the metal For very rapid response and for accuracy it is an advantage to measure the temperature of the metal enclosure with a resistance thermometer wound directly on to it or with a directly attached thermocouple

The crystalline substance should be in the form of a single crystal or a transparent group of crystals, a group containing many fissures will slowly take up or liberate relatively large amounts of water Crystals suitable for most purposes include potassium sulphate, sodium chloride, calcium chloride and lithium chloride, which possess equilibrium relative humidities of approximately 99, 76, 30 and 15 per cent, respectively With potassium sulphate, for example, cooling will generally be necessary, whereas with lithium chloride heating is necessary except for relative humidities less than about 15 per cent, reckoned at ambient temperature Although used for convenience in the initial experiments, sodium thiosulphate is not an ideal choice since it reacts sensitively with acid vapour and even carbon dioxide

For manual operation the conductivity may be indicated directly on a deflecting instrument For automatic operation the resistance of the crystal may be made, by electronic means, to govern the heating or cooling of the metal enclosure Any such automatic system contains a perfect integrating link on account of the condensation process and must, therefore, give the true equilibrium temperature, however, the design must ensure that, for the maximum amplification consistent with stability, the response of the system is sufficiently rapid

A hygrometer constructed in accordance with the above principles has been used with crystals of a number of salts Experience with this instrument has shown that the method is reliable, accurate and rapid When the equilibrium temperature is already known approximately, the time required to obtain a balance to ± 0 01 deg C is about one minute. The vapour pressures of saturated salt solutions are, however, not in general known at present with an accuracy higher than the equivalent of ± 0 1 deg It should be mentioned that an accuracy of ± 0 01 deg, corresponding approximately to ± 0 1 per cent relative humidity, can be utilized fully only when the departure of the behaviour of a mixture of air and water vapour from the laws for a perfect gas mixture is taken into account

Surface contamination of the crystal has not been found to be a serious problem If present, it can readily be detected and its effect on the measurement eliminated by observing the balance temperatures for two widely different values of the resistance of the crystal unit and extrapolating to zero resistance Soluble surface contamination which has not originated from impurities in the crystal substance is easily removed with water

In some cases small jumps in the resistance, which probably resulted from electrode effects, have been observed Any effects due to electrode phenomena can be eliminated by using four contacts on the crystal, representing current and potential connexions, or by using high-frequency methods with two electrodes spaced from the crystal For most purposes the use of such methods is unlikely to be necessary

Applications

The method provides a convenient substitute for the dew-point hygrometer It is more accurate and more amenable to instrumentation In contrast with the dew-point method, it allows accidental contamination of the surface to be detected easily It is readily applicable to measurements on gases at very high pressures With a crystal of calcium chloride, the useful range is continuous down to −55° C Provided that the gas reaching the hygrometer is of constant composition and that the crystal is reasonably pure and is held by clean, well-formed electrodes, the ultimate accuracy is probably determined by the limitations of precise thermometry

The instrument obviously provides a powerful tool for the accurate measurement of the vapour pressures of saturated salt solutions as a function of temperature It is proposed to use as a standard substance potassium sulphate, the saturated solution of which provides a relative humidity of about 99 per cent, and work is in progress to determine accurately the vapour pressure – temperature relationship of a saturated solution of this substance relative to the vapour pressure of water It is intended then to determine the vapour pressure curves for a number of stable salts, using each in turn for the hygrometer crystal element

The method will be used for providing the standard of reference for the testing of hygrometers at the National Standards Laboratory in Sydney Work is at present in progress on a rapid automatic instrument to be used as the humidity-sensitive unit for the accurate control of atmospheres in researches on biological materials in other laboratories of the Organization

A detailed account of the hygrometer will be published elsewhere I wish to acknowledge the work of Mr W van Peer in constructing the electronic resistance-measuring unit and in assisting with the experiments

Specificity of Creatine Phosphokinase

SOME of the properties of the enzyme creatine phosphokinase have recently been described[1], but no experiments were reported on the activity of the enzyme with substrates other than adenosine triphosphate, adenosine diphosphate, phosphocreatine and creatine Such experiments are in progress and will be reported in due course A recent publication by Armstrong[2], in which it was shown that the administration of N-ethylglycocyamine (negmine) was followed by the urinary excretion of N-ethylglycocyamidine (negmidine), suggested that a phosphorylation reaction may have been involved It was therefore of interest to determine whether negmine could be phosphorylated by the creatine phosphokinase system

Some experiments have been carried out with a system similar to that already described[1] for the reaction

$$\text{ATP} + \text{creatine} \rightarrow \text{PC} + \text{ADP},$$

but differing in that negmine was substituted for creatine and the temperature was controlled at 30° The course of the reaction was followed by removal of samples at various time-intervals after the addition of adenosine triphosphate to the system, and determinations of negmine were made by the same method as that used for creatine[1]

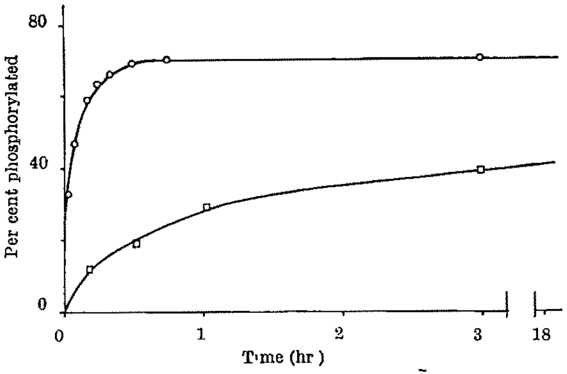

Fig 1 Rate of phosphorylation of creatine (○—○) and negmine (□—□) by the creatine phosphokinase – adenosine triphosphate system

It will be noted that negmine was phosphorylated, but at a much slower rate than was creatine On the other hand, the amounts of each which were phosphorylated in the maximum time-interval investigated (18 hr) were not greatly dissimilar

The product of the reaction, phosphonegmine, was not isolated, but its properties (Table 1) are similar to those of phosphocreatine in the ease with which it may be hydrolysed under mild conditions (9 min, 0 1 *N* hydrochloric acid, 65°) It will also be noted that, as with creatine, there is an almost quantitative recovery of negmine following hydrolysis.

Table 1 RECOVERY OF CREATINE AND NEGMINE BY HYDROLYSI FOR 9 MIN AT 65° IN 0 1 *N* HYDROCHLORIC ACID AFTER REACTIO WITH CREATINE PHOSPHOKINASE – ADENOSINE TRIPHOSPHATE FO 18 HR

	Initial	Final (18 hr)	Final (after hydrolysis)
Creatine (μmoles)	20 0	7 2	19 6
Negmine (μmoles)	20 0	8 0	19 6

The fact that negmine may be phosphorylated by the creatine phosphokinase – adenosine triphosphate system is of importance, for, since the administration of glycocyamine is not followed by the excretion of glycocyamidine, and since glycocyamine is not phosphorylated by this system[3], it may be inferred tha creatinine does arise from phosphocreatine[4,5]. Thi does not, however, provide proof of the hypothesis that creatinine arises as a result of the non-enzymi breakdown of phosphocreatine The results als confirm the belief[2] that the urinary excretion o negmidine followed the *in vivo* formation of phospho negmine.

The complete results of this investigation will b reported in greater detail elsewhere

Mode of Action of Tetanus Toxin

THOUGH the general effects produced by tetanus toxin on the nervous system have been reported by many investigators, there is still no precise evidence as to its mode of action[1] Sherrington[2] pointed out that tetanus toxin closely resembles strychnine in many of its effects, and postulated that both substances convert synaptic inhibition into excitation Recently[3], it has also been found that tetanus toxin resembles strychnine in that the monosynaptic tendon jerk is but little affected by moderate dosage Since it has now been shown that strychnine acts specifically by diminishing all types of synaptic inhibitory action[4,5], it was of interest to investigate the action of tetanus toxin on synaptic inhibition.

The tetanus toxin was administered by injection within the sheath of the sciatic nerve in order that its effect on the spinal cord would initially be localized, and hence control responses would be provided by the other side The procedure for investigating direct inhibition resembled that already described[4], single maximum volleys in the large stretch afferents from quadriceps muscle being employed to inhibit the monosynaptic reflex discharges which were evoked from biceps-semitendinosus motoneurones at varying testing intervals thereafter. In Fig 1 the inhibitory curves so constructed at 21–43 hr after the injection of the toxin give a typical illustration of our experimental findings The earliest test, at 21 hr, revealed that the inhibition amounted to 65 per cent, in

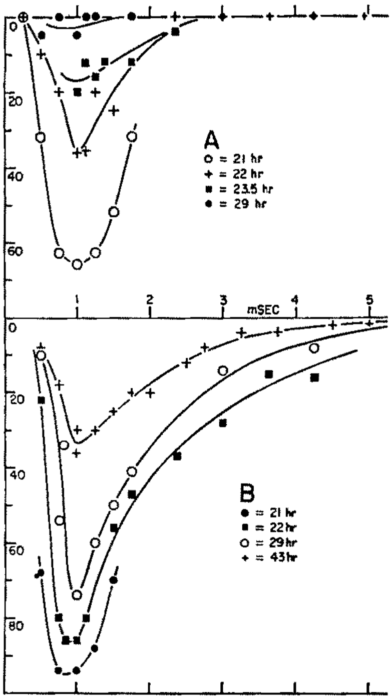

Fig 1 Curves showing time courses of direct inhibition of monosynaptic reflex from biceps-semitendinosus motoneurones of the spinal cat under light 'Nembutal' anæsthesia The symbols denote the inhibitory effects observed at the times indicated after the injection of 7 mgm of tetanus toxin (Wellcome *XB* 1322 *T* 166) in 0 05 ml normal saline under the sheath of the left sciatic nerve at the mid-thigh level Figs 1 *A* and *B* were obtained respectively on the left and right sides The percentages of inhibition of the monosynaptic reflex spike (ordinates) are plotted against the various intervals (in m sec) by which the testing excitatory volley follows the initial inhibitory volley (abscissæ) Each plotted percentage is the mean of ten to twenty observations

contrast to 95 per cent on the contralateral side. Subsequent tests at 22 and 23½ hr. showed the rapid diminution of the inhibition to about 35 and 15 per cent respectively, while it was still little affected on the contralateral side By 29 hr the respective inhibitions were less than 5 per cent and about 75 per cent The slow diminution of the contralateral inhibition was kept under observation until it was only about 35 per cent at 43 hr , while on the ipselateral side all trace of inhibition had disappeared many hours earlier During all this period the testing monosynaptic reflex spike showed little change in size and remained virtually the same on the two sides Thus the experimental series of Fig 1 shows typically that tetanus toxin resembles strychnine in that it selectively suppresses inhibitory action, while synaptic excitatory action is unaffected.

All other types of inhibitory action in the spinal cord have similarly been suppressed by tetanus toxin and strychnine. It has further been found that tetanus toxin has no effect on the synaptic relays that occur on the direct inhibitory pathway[6] and on the antidromic inhibitory pathway[5]. Finally, intracellular recording from motoneurones has indicated that the inhibitory hyperpolarization is suppressed by tetanus toxin, exactly as occurs with strychnine Thus there are two likely explanations of the action of tetanus toxin that, like botulinum toxin, it may prevent the release of the transmitter substance[7] , or that, like strychnine, it may become attached to the subsynaptic inhibitory areas on the motoneuronal membrane, preventing the action thereon of the inhibitory transmitter

Besides acting as a control, the contralateral observations (Fig 1*B*) illustrate the slow spread of the action of tetanus toxin in the spinal cord that has been reported by previous investigators[1-3] Inhibition in the segment rostral to that illustrated in Fig 1 showed much the same slow development of inhibitory depression as in Fig 1*B*, the inhibitory effect being halved at about 30 hr Concurrently with the gradual suppression of inhibitory action, there was a large development of polysynaptic reflexes, similar to that produced by strychnine This effect could be satisfactorily explained by the depression of inhibitory synaptic action on the interneurones of these polysynaptic pathways, that is, tetanus toxin appears to depress inhibitory action on interneurones as well as on motoneurones

It may be concluded that, in confirmation of Sherrington[2] the action of tetanus toxin on the spinal cord closely resembles that of strychnine , but both these substances act, not by converting synaptic inhibition into excitation, but by suppressing all types of synaptic inhibition It is probable that general tetanus is also similarly explained by the general suppression of synaptic inhibitory action as the tetanus toxin spreads throughout the whole nervous system

Effect of Background Activity on the Action of Acetylcholine on the Electrical Activity of the Brain

RECENT experiments have led to the suggestion[1] that the physiological action of acetylcholine on the activity of the brain might be conditioned by the state of excitation of the brain itself

As a preliminary test of this possibility, two series of experiments have been carried out on rats, rabbits and cats In the first series, electroencephalograms were recorded from needle electrodes in the intact skull, and acetylcholine was rapidly injected into the internal carotid artery In the second series, a 'Perspex' irrigation chamber was fixed tightly into a trephine hole in the skull, and Ringer–Locke solution—to which acetylcholine could be intermittently added —was passed slowly through the chamber The electroencephalogram was recorded from a fine electrode, insulated to the tip, in contact with the exposed cortex. When administered by either route, to an animal anæsthetized with 'Dial', acetylcholine caused, as was expected, excitation with small doses and depression with larger doses, the threshold dose for excitation being, for intracarotid administration in the rabbit, of the order of 1–2 μgm In irrigation experiments the doses required were higher (25 μgm.

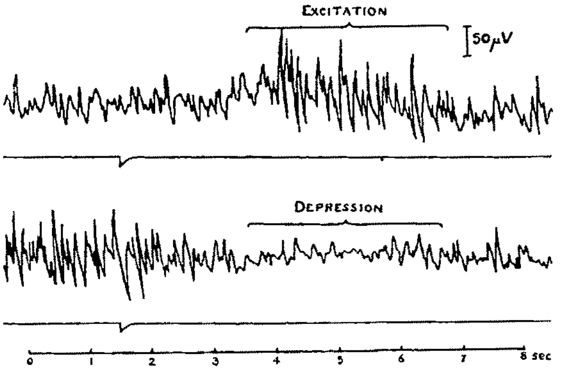

Fig. 1. Electroencephalogram record from exposed irrigated cortex of rabbit. Upper tracing, animal under 'Dial' alone, lower tracing, animal under 'Dial' + leptazol. At signal, acetylcholine (25 μgm.) added to irrigation fluid: excitatory action of acetylcholine on quiescent cortex, depressant effect on activated cortex

for excitation), but the effects were qualitatively similar.

When the cortex of the anæsthetized animal was activated by the intraperitoneal injection of 'Leptazol' (80 mgm./kgm.), doses of acetylcholine which were previously excitatory became inhibitory, a typical result being illustrated in Fig. 1. Doses previously ineffective remained so, while the inhibitory effect of larger doses became less well marked.

The addition of adrenaline (10^{-4} M) to the Ringer–Locke solution irrigating the exposed cortex caused a significant reduction in the threshold dose of acetylcholine required for excitation or inhibition.

None of the effects mentioned could be attributed to the vascular actions of acetylcholine.

This work will be described more fully and discussed elsewhere.

Long-term Suppression of a Permeability Response of the Rat's Hind-paw by Cortisone, by Hypophysectomy and by Protein-deficient Diet

Some three years ago, we reported that crude testicular extracts containing hyaluronidase greatly increase permeability in the rat's hind-paw[1]. 0.3–0.8 mgm. of crude extract is dissolved in 0.11 ml. saline and injected at the plantar side; each animal serves as its own control. The acute œdema—surpassing that caused by the usual doses of dextran—contains 4.0–5.5 gm. protein per 100 ml. The presence of histamine was demonstrated by the guinea pig ileum test as well as by partition paper chromatography, the concentration being 2.5–4.5 μgm. per ml. The significance of this histamine, as well as the influence of local reactivity of the tissues of the hind-paw, and the influence of age differences will be discussed separately. We find that young rats regularly show 'full' œdemas in our colony, although the response tends to diminish gradually with advancing age.

In earlier papers[2-4] we dealt with the possibilities of influencing permeability in acute experiments. Pharmacological doses of salicylate, of natural adrenaline, etc., inhibited remarkably the production of œdema. The significance of the presence of the adrenal glands, as well as the importance of circulatory factors, were emphasized.

In the present communication we are dealing with the long-term changes in this permeability response. Each of three groups of experiments relates to 25 animals, or more.

(*a*) Cortisone (subcutaneous) was a potent material inhibiting œdema[5]. The dose necessary to produce full inhibition, however, was remarkably high. About 10 mgm. per 100 gm. for the adult rat and 10–20 mgm. for rats weighing less than 100 gm. was the effective dose if single injections were given. The protection against œdema mostly appeared on the second day, or even later; but it was demonstrable for several days or even a week. The massive dose of 50 mgm. cortisone acetate subcutaneously per 100 gm. rat inhibited œdema induced by testicular extract for a month.

(*b*) A second type of long-term suppression of œdema production of the hind-paw was that of hypophysectomized animals. The time of appearance of this change in permeability response varied; but animals with perfectly evacuated sella mostly failed to react with a sufficient œdema from one to four weeks after the operative procedure until death. It is to be noted that cases were observed with returning response; but hypophysial residue was detected in these cases with the lack of atrophy of endocrine organs. A remarkable lack of permeability response could be thus produced without any hypophysio-adrenocortical activation and/or in the absence of effective amounts of cortisone.

(*c*) As the greatly diminished response of the chronically hypophysectomized rats could certainly not be explained by cortisone action, we searched for a possible common explanation. Alteration of the protein metabolism seemed to be the possible common pathway. The third group of animals, thereafter, consisted of young normals held on a protein-deficient diet containing foodstuffs with the protein content less than 2.0 per cent. No other constituent was restricted. An example of this type of experiment (16/17, five rats) is as follows: body-weight 50–75 gm.; average body-weight decrease after 15 days, 10 per cent.; average caloric intake, 19.9 cal. a day each rat; per cent of protein calories, 9.2. About 15–25 days later the grade of the acute œdema was very slight, if any. All animals were 'hyporeactors' from this point of time, and the response did not return until normal, or protein-rich, diet was introduced. This latter, however, evoked a quick return of the original reaction, that is, within 24–72 hr. More time is needed, however, to restore normal response, if the dietary protein deficiency is maintained for several days. Like the animals of groups (*a*) and (*b*), the growth of these young rats ceases, and a moderate diminution in the body-weight is the rule. The plasma protein concentration did not change significantly.

The present results are not opposed to the possibility that dehydration of the connective tissue (that is, a shift of water from the cells into the extracellular compartment and simultaneous phenomena, including eventually alterations in the metabolism of the cement-substances) may be important in the effects produced by the protein-deficient diet. Based on these observations, the explanation of the influence of pharmacological doses of cortisone, at least that exerted on permeability mechanisms, seems to be in the field of the alterations of protein metabolism and its consequences Similar changes are apparent after hypophysectomy Our results suggest that long-term suppression of permeability is attainable, if the metabolism of water-binding molecules is altered, whereas only transitory suppression results if dehydration is produced without long-term influencing of water-binding macromolecules

Details of these experiments will be published in *Acta Medica Hungarica*

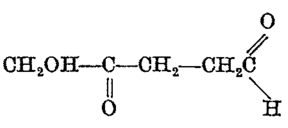
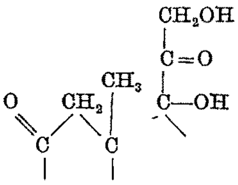
A Colorimetric Reaction for the Estimation of Cortisone, Hydrocortisone, Aldosterone and Related Steroids

IT was shown by Stacey *et al* [1] that one of the substances responsible for the development of colour in the Dische reaction[2] for deoxynucleic acid is ω-OH-lævulinic aldehyde Slight changes in this molecule resulted in the development of different colours An examination of the formulæ of cortisone and hydrocortisone shows the presence of reactive groups similar to those of ω-OH-lævulinic aldehyde



ω-OH-lævulinic aldehyde



Part of cortisone structure

Both compounds have terminal ketol groups and a carbonyl group five or six carbons distant from the primary alcohol group

Accordingly, the diphenylamine reagent, suitably modified to improve the intensity of the reaction, was applied to various steroids (*A*) Reagent mixture 54 ml of glacial acetic acid , 6 ml of concentrated sulphuric acid , 10 ml of distilled water , 600 mgm diphenylamine (*B*) Blank mixture contains the same reagents except that diphenylamine was omitted

Depending upon the nature of the steroid, 10–50 γ of material may be determined in a micro-procedure using 1 ml of reagent, and 50–400 γ using 3 0 ml of reagent

Two equal aliquots of the steroid solution are evaporated to dryness in test-tubes To one test-tube is added reagent mixture and to the other an equal volume of blank mixture The test-tubes are then heated in a boiling water-bath for 1 hr to obtain maximum development of colour The solutions are cooled to room temperature in running tap water and are observed in a Beckman spectrophotometer, either model *B* or *D U* The colours are stable for several hours and obey Beer's law in the ranges tested, namely, 10–400 γ. The instrument is set at zero optical density with the blank mixture, and the optical density of blank mixture plus steroid is observed The instrument is now set at zero optical density with the reagent mixture, and the optical density of reagent mixture plus steroid is observed The difference between the optical density of reagent mixture plus steroid and the optical density of blank mixture plus steroid is a measure of the amount of steroid present

Table 1

Steroid (200 μgm in 3 0 ml)	Colour
Corticosterone (compound *B*)	yellowish-green
Deoxycorticosterone	faint yellow
17-OH-Corticosterone (hydrocortisone)	green
Hydrocortisone acetate	green
17,21-Dihydroxy-(3,20-dione)-$\Delta^{4,9}$-pregnadiene (anhydro *F*)	green
3α,11β,17,21-Tetrahydroxypregnane-20-one (tetrahydrohydrocortisone)	green
17-OH-11-Deoxycorticosterone (substance *S*)	green
11-Dehydrocorticosterone (compound *A*)	violet
21-Hydroxypregnane-3,11,20-trione (dihydro *A*)	faint pink
3α,21-Dihydroxypregnane-11,20-dione (tetrahydro *A*)	colourless
17-OH-11-Dehydrocorticosterone (cortisone)	violet
Cortisone-21-aldehyde	violet
Cortisone acetate	violet
3α-17,21-Trihydroxypregnane-11,20-dione (tetrahydrocortisone)	violet
Δ^6-Dehydrocortisone acetate	violet
Progesterone	faint yellow
11-Ketoprogesterone	faint yellow
11-β-OH-Progesterone	faint yellow
6β-OH-Testosterone	colourless
Δ^4-Androstene-3,17-dione	faint yellow
Δ^4-Pregnene-11β,21-diol-3,20-dione-18-al (aldosterone)	blue

The colours obtained with different steroids are shown in Table 1 Although some steroids gave no visible colour with the amounts used, all absorbed to some extent The curves in Fig 1 show the absorption spectra of the steroids after the blank values are subtracted

Those steroids that contained keto-groups at the 11 and 20 positions and hydroxyl groups at the 17 and 21 positions gave similar characteristic absorption curves with a maximum at 530 mμ These compounds gave distinct violet colours The elimination of the hydroxyl in position 17 as in compound *A* merely decreased the intensity of colour without changing the shape of the curve Increased saturation of the compound as in the 'dihydro' or 'tetrahydro' forms decreased the intensity of colour

Those steroids that contained hydroxyl groups at positions 11, 17 and 21 and a ketone at position 20 gave a green colour with a maximum absorption in the range of 630–650 mμ Again, saturation, as in 'tetrahydrohydrocortisone' or the absence of the 17-OH group, decreased the intensity of colour However, substance *S*, which has a hydroxyl in position 17 instead of in position 11, gave almost the same absorption as hydrocortisone

Fig 1 also shows the absorption spectrum of approximately 50 γ of aldosterone (kindly supplied by L H Sarett, of Merck and Co , Inc) The maximum at 640 mμ indicates the presence of a hydroxyl group at C_{11} In addition, there was a peak at 530 mμ and a negative value at about 450 mμ This compound gave a distinct blue colour which was not obtained with any of the other steroids tested

Steroids of the progesterone and testosterone type gave practically no absorption at 530 mμ or 630–650 mμ, as compared with cortisone or hydrocortisone.

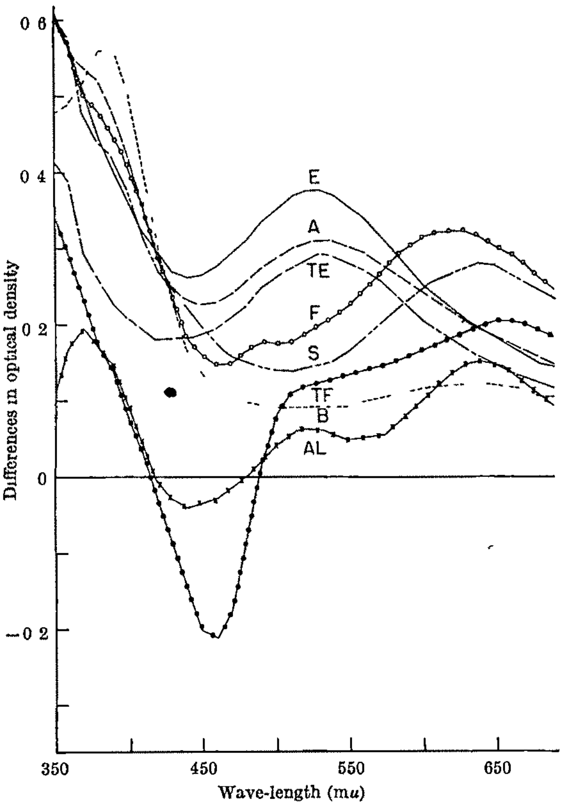


Fig 1 (*E*) Cortisone (17-OH-11-dehydrocorticosterone), (*A*), Compound *A* (11-dehydrocorticosterone), (*TE*), Tetrahydrocortisone (3α-17,21-trihydroxypregnane-11,20-dione), (*F*), Hydrocortisone (17-OH-corticosterone), (*S*), Substance *S* (17-OH-11-deoxycorticosterone), (*TF*), Tetrahydrohydrocortisone (3α,11β,17,21-tetrahydroxypregnane-20-one), (*B*), Compound *B* (corticosterone), (*AL*), Aldosterone (Δ^4-pregnene-11β,21-diol-3,20-dione-18-al)

The substitutions essential for the violet colour and the characteristic absorption spectrum of cortisone and similar steroids are (1) a hydroxyl at C_{21}, (2) keto-groups at C_{11} and C_{20} Those necessary for the development of the green colour and characteristic absorption spectrum of hydrocortisone and related steroids are (1) hydroxyl groups at C_{21} and C_{11} or C_{17} and (2) a keto-group at C_{20}

Since different absorption maxima are obtained with cortisone and hydrocortisone, it is possible to calculate the amounts of both substances by using the maximum absorption value of cortisone and the isosbestic point of the two steroids This can also be done with mixtures of any two steroids if one reacts similarly to cortisone (for example, compound *A*) and the other similarly to hydrocortisone (for example, compound *B*)

The negative value observed with 'tetrahydrohydrocortisone' (Fig. 1) appears to be characteristic of this substance and can be used for identifying it in mixtures of steroids. It is the result of a reaction between this steroid and the blank mixture. Similar reactions occur between the other steroids and the blank mixture, particularly substance *S*, compound *B* and hydrocortisone, but none of these causes any significant interference in the range 500–650 mμ.

Of the steroids listed in Table 1, it is doubtful if many will appear simultaneously in biological fluids such as blood or urine. If the mixture is not too complex, the eleven oxygenated steroids may be determined in the presence of the 11-hydroxylated steroids. This method, with an appropriate extractio is being applied to biological material and will b reported in the near future

Differences between Rates of Metabolism of Benzene Hexachloride in Resistant and Susceptible Houseflies

In a previous communication[1], the metabolism γ-BHC was described after injection into three strai of flies a susceptible strain (*S*), a strain resistant γ-BHC (R_1), and a strain resistant to γ-BHC a DDT (R_2)

The rate of metabolism in the susceptible stra was not comparable with that of the resistant strain since the former died rapidly, whereas the latt remained unaffected. Thus it was impossible to te whether the difference in metabolism could be cause of the difference in susceptibility

Hitherto, the method of estimation did not perm the study of the metabolism at doses low enoug to leave also strain *S* unaffected. However, th problem becomes accessible for experimentation if w assume that all isomers of BHC are metabolized b the same mechanism Then the breakdown in th strains can be studied in comparable circumstance as it is possible to estimate the α- and δ-isomer a concentrations that are not at all toxic to the flie

The flies were injected into the thorax with BH in an emulsion of peanut oil, and kept at 25° C f varying periods of time, after which the amount BHC was estimated The results are presented Fig 1 and Table 1. It is shown that there is a diffe ence in breakdown of the α- and δ-isomer betwee the susceptible and resistant strains This differen is somewhat larger in the case of the α-isomer. Th breakdown of the δ-isomer is markedly slower tha that of the α-isomer. As for technical reasons th experiments were not extended beyond 24 hr., was impossible to obtain the complete breakdow curve for this isomer

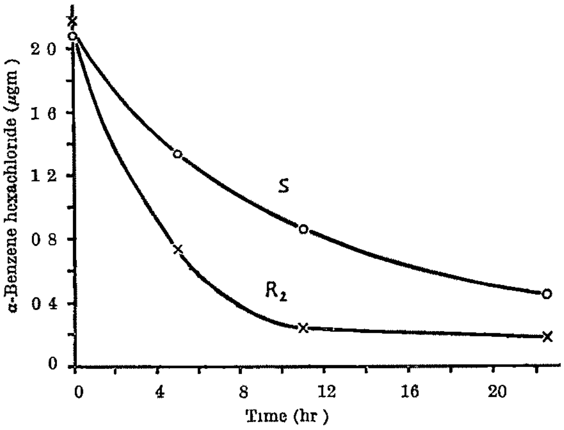

Fig 1 Amount of α-BHC per fly plotted against time after injection *S*, susceptible strain, R_2, γ-BHC and DDT-resistant strain Fifteen flies used for each estimation

Table 1 BREAKDOWN OF α- AND δ-BHC
'hirty flies used for each estimation, horizontal lines represent injections on the same day

Isomer	Amount injected per fly (μgm)	Time between injection and estimation (hr)	Breakdown (per cent) S	R_2	R_1
α	0 83	4	36	60	80
	0 93	4	36	57	57
	0 67	4	45	55	65
	2 34	5	34	—	57
	2 34	5	43	—	71
	2 34	5	40	57	—
	2 34	5	23	50	69
δ	2 34	18½	28	43	—
	2 34	18½	29	32	—
	2 34	18½	25	32	—
	2 34	18½	27	46	47
	2 34	18½	27	39	37

If our hypothesis is correct, the difference in rate of breakdown of γ-BHC between the susceptible and resistant strains has two causes (1) a difference in breakdown capacity—a possible cause of difference in susceptibility, (2) a decreasing rate of breakdown in the susceptible strain as a result of the toxic action of γ-BHC—an effect of the susceptibility.

If we assume that the metabolism results in a detoxication, it is very probable that the difference in metabolism is a cause of the difference in susceptibility, although it is as yet impossible to estimate its importance For example, it is not known how the rate of breakdown affects the concentration at the site of action. Work with more strains will perhaps be helpful in judging the significance of rate of breakdown for resistance, as it may reveal whether there exists a correlation between capacity of breakdown and level of resistance.

Lysis of Human Pathogenic Bacteria by Myxobacteria

ALTHOUGH great interest has been taken in recent years in isolating antibiotics from various groups of micro-organisms, Myxobacteria have received so far very little attention Several workers have reported the lysis of bacteria (Eubacteria) by species of Myxobacteria , but no satisfactory evidence has been produced that living cells are attacked It has been shown by Singh[1], who used a large number of strains of bacteria, that certain species of Myxococcaceae undoubtedly cause lysis of both Gram-positive and Gram-negative living bacteria upon solid media Oxford and Singh[2] and Oxford[3] have shown that a strain of *Myxococcus virescens* growing on cell-free medium is able to produce two substances, an exocellular lytic (proteolytic) enzyme and an antibiotic Noren[4] has confirmed and extended this work to other species of Myxobacteria and has devised more suitable media for the production of the proteolytic enzyme and the antibiotic. The present work deals with the lysis of human pathogenic bacteria by two species of *Myxococcus*.

A strain of *Myxococcus virescens* and *M. fulvus* was tested on strains of bacteria by Singh's method[1] In all the experiments twenty-four hour old cultures of bacteria, grown at 37° C on nutrient agar slopes, were used Two streaks (about 1 in long) well separated from each other, of a bacterium to be tested, were made on a non-nutrient agar plate (1 5 per cent agar, 0 5 per cent sodium chloride , *p*H 7 0). One of the streaks was inoculated at one end with fruiting bodies of a Myxobacteria growing on living *Aerobacter* sp and the other was left as control The culture was incubated at 37° C and examined at 2–6 days.

Table 1 shows the lysis of bacterial strains by two species of Myxobacteria. Of the bacteria tested by the above method, some were readily or slowly but completely lysed, others showed partial lysis and *Mycobacterium phlei* was not lysed The dysentery, cholera and typhoid groups of organisms were attacked to varying degrees *Shigella sonnei*, *S. paradysenteriae* Flexner, *Vibrio cholerae* Ogawa 49514, *Salmonella typhosa* and *S typhosa* Vi–*I* were completely lysed by *M virescens* and only partially by *M fulvus* *V. cholerae* Rough 49515 was, however, lysed completely by the latter and only partially by the former

Table 1 LYSIS OF BACTERIAL STRAINS BY MYXOBACTERIA

Bacterial strains tested	*Myxococcus virescens*	*Myxococcus fulvus*
Staphylococcus aureus	*Pl*	*Pl*
Bacillus subtilis	*Pl*	*Pl*
Mycobacterium phlei	*Nl*	*Nl*
Shigella dysenteriae Shiga	*Pl*	*Pl*
S sonnei	*Cl*	*Pl*
S paradysenteriae Flexner	*Cl*	*Pl*
Vibrio cholerae Ogawa 49514	*Cl*	*Pl*
Vibrio cholerae Rough 49515	*Pl*	*Cl*
*Proteus X*19	*Cl*	*Cl*
Salmonella paratyphosa	*Cl*	*Cl*
Salmonella typhosa	*Cl*	*Pl*
Salmonella typhosa O-901	*Pl*	*Pl*
Salmonella typhosa H-901	*Cl*	*Cl*
Salmonella typhosa Vi–*I*	*Cl*	*Pl*

Cl = completely lysed either readily or slowly , *Pl* = partial lysis , *Nl* = not lysed

In order to find out whether the rate or the extent of lysis of the susceptible pathogenic bacteria (Table 1) by Myxobacteria could be improved, *M virescens* and *M. fulvus* were grown and subcultured a few times on the same organisms No marked difference in the lysis of the organisms was observed as compared with the results presented in Table 1.

M virescens and *M fulvus* were grown on non-nutrient agar plates with *Aerobacter* sp and *Staphylococcus aureus* at 26°, 30° and 37° C The growth of Myxobacteria was better at 30° and 37° C. than at 26° C., the effect being more marked in the case of *M. fulvus* The temperature-range of 30°–37° C was also more favourable for the production of fruiting bodies of Myxobacteria. This is in accord with the findings of Noren

Our thanks are due to Dr. B N. Singh, assistant director, Microbiology Division, of this Institute, for his interest in this work

Relationship of Ovarian Hormones to the Pyogenic Effect of *Corynebacterium pyogenes*

Rowson, Lamming and Fry[1] and Lamming and Rowson[2] have reported that purulent infections rapidly become established in the uterus of the cow following introduction into the uterus of infected bull semen or cultures of *C pyogenes* during the luteal phase of the œstrous cycle, but infections introduced into the uterus of cows in œstrus fail to become established Using ovariectomized cows, the resistance and susceptibility of the bovine uterus to infection was shown to be due to the action of œstrogens and progesterone respectively The possibilities suggested to account for the variation in resistance to infection include (*a*) an increase in leucocyte activity during œstrus, (*b*) an increase in antibody activity during œstrus, (*c*) the production in the uterus during the luteal phase of an environment suitable for rapid bacterial development The present work is concerned with the effects of the uterine environment

Uteri were removed at slaughter from cows and rabbits which were in the luteal phase and from cows during the follicular phase and in anœstrus, and from rabbits injected one day previously with 10 mgm stilbœstrol and in anœstrus Using aseptic precautions, blood samples were also collected from the rabbits by heart puncture and from the cows by bleeding from the jugular vein Blood samples were also collected from cows during the luteal phase, in œstrus, and from pregnant cows

The primary aim of the work was to establish whether or not the uterus of the œstrous animal contained substances which were antibacterial in action Using aseptic precautions, the uterine mucosa of cows and rabbits was exposed and a small circle (0 5–2 0 cm diameter) of sterile filter paper was pressed against the uterine mucosa to make a swab Two swabs from each animal were placed on horse blood agar inoculated with *C pyogenes* In some cases additional swabs from cow and rabbit uteri were placed on rabbit blood agar or cow blood agar containing *C. pyogenes.* Small strips of uterine mucosa from both species were also placed in horse-, cow- or rabbit-blood agar plates with and without *C. pyogenes.* Rabbit blood was obtained by heart puncture from animals injected intramuscularly one day previously with 10 mgm. stilbœstrol, and blood samples were obtained both from pregnant cows and those in the œstrous and luteal phases. Two or three drops of plasma, or whole blood, on separate sterile filter disks were placed on horse blood agar plates with and without *C pyogenes*

Preliminary results using strips of uterine mucosa and swabs of uterine fluid showed an increased zone of hæmolysis, 3–5 mm wide, on horse blood agar plates containing *C. pyogenes* when the tissues or swabs were taken from either a cow in the follicular phase, an anœstrous cow, or a rabbit treated with stilbœstrol There was no zone of hæmolysis on horse blood agar plates containing *C pyogenes* when the uterine tissue or swab originated from either an anœstrous rabbit, cows in the luteal phase or in rabbits 3–6 days post-ovulation There were no zones of hæmolysis on horse, cow or rabbit blood agar plates without *C pyogenes* whatever the origin of the tissue or swabs

That a combination of *C pyogenes,* horse blood agar and material taken from an animal during a particular phase of reproductive activity will cause increase hæmolysis is unusual and interesting The zones of ir creased lysis occurred when tissues or blood plasm were taken from animals which, on the basis of th earlier work, would be expected to be resistant to ex perimental uterine infections It seems probable tha these zones of increased lysis are not associated wit more active growth of the test organism That th zones of increased lysis can be demonstrated usin blood plasma as well as uterine swabs and uterin tissue suggests that a general physiological effec may be present Work is continuing to decide whethe the effect is due to specific antagonistic or stimulator effects of the sex hormones, or their analogues.

Competition among Wild Rats

Observations in the field and in large enclosure have shown that feral rats (*Rattus norvegicus* Berkenhout), unlike albinos of this species, display, in a highly developed form, both territorial and othe types of competitive behaviour[1–3] Interspecifi competition, between *R. norvegicus* and *R rattus* L has also been directly observed[2] These studies have however, thrown little light on the exact circum stances which evoke competition, or on the precis nature of the behaviour involved

Colonies of both species of rats have been main tained in cages of about 1 cu m, with attached nes boxes Cinematograph films have been taken of som colonies in a cage with a glass front. The rats wer marked with a depilatory In these conditions, group of adult males of both species, trapped in Glasgo or bred from rats so trapped, have lived for up t twenty-two weeks without mortality, and usuall without injury Generally, several individuals slep together in a nest box, without distinction of species Thus competitive behaviour is not necessarily evoke by the presence of another male, or by a member o a closely related species. In these experiments al the males were introduced, at the same time, into ar unfamiliar cage However, as described also else where[2], *R norvegicus* males newly introduced intc an established colony were often persecuted b members of their own species some died within a few days This type of competitive behaviour is evidently the result of the establishment of a territory Females of both species will also live together without conflict Non-parturient females differ from males however, in not showing territorial behaviour

R norvegicus males, put in cages together wit females of the same species, fight vigorously In the first of such experiments only one (the heaviest) out of six males survived after eleven weeks Contro males, litter mates of the experimental animals, kept singly in small cages each with one female, showed no mortality, these pairs have produced many viable litters Females do not fight as males do, and they nearly always survive the experiments without injury They readily become pregnant during the experiments, but there is a high mortality among the nestlings. Thus competition in this species is markedly different in the two sexes, and it can be evoked among males by the presence of females.

Fighting does not involve serious wounding to either rat involved, though vigorous, it is formal rather than, in itself, lethal. Injuries may include superficial damage to tail or ears, or occasionally to limbs, sometimes the skin is torn in the neck region. Deaths appear to be due to exhaustion rather than to wounding, and sometimes occur without detectable external damage. In the male–female colonies, the weights of some males rose during the experiments, but the weights of most fell. All the control males in small cages increased in weight. The experimental males which grew most tended to be those which were initially heavier than the rest, some of these successful males grew more than any of the controls.

Adrenal glands of males used in these experiments were removed, weighed and examined histologically. The adrenal cortex of subordinate rats involved in severe fighting over short periods, for example, two days, showed marked depletion of sudanophilic material, such as is found also in other forms of 'stress'[4]. On the other hand, subordinate males examined after some weeks of exposure to moderate competition showed little or no depletion, in these, however, there was evidence of hypertrophy of the adrenal cortex, since the relative weights of their adrenals were higher than those of the controls. Dominant males, which had fought just as much, or more than, the depleted subordinate males, showed no depletion. This suggests that the exhaustion of subordinate males is not merely a consequence of violent exercise, but also involves more complex nervous and endocrine changes.

The method described here allows detailed observation and filming of the social behaviour of marked rats, and makes it possible to relate the behaviour seen to physiological changes revealed at autopsy. The results indicate that competition among wild rats is evoked by a number of quite specific situations, which can be analysed by experiment in the laboratory. Full accounts of this work will be published elsewhere.

Black Grub Infection in *Catla catla*

More than 150 fingerlings of the fish *Catla catla* (Ham. Buch.) collected in July 1953 from freshwater sources in Samalkot, East Godavari District, Madras, were heavily infested with black grub cysts embedded under the skin and distributed all over the body. In one specimen, more than three hundred cysts were encountered. Cysts were excised and ruptured under a coverslip to release the larva, with or without its own envelope, and its organization studied by clearing it with phenol.

The black colour is due to the dendritic pigmentation on the fibrous, elliptical host-cyst, inside which floats the colourless larva invested by a gelatinous parasite-cyst. The parasite proved to be a metacercaria of a strigeid trematode.

Its structural details (Fig. 1) are briefly as follows: body typically bi-lobed, with almost equal halves, the fore-body filled with glands and less transparent than the hind-body, oral sucker broader than long, pharynx elongated, œsophagus narrow and slender, and intestinal cæca extending far into the hind-body, accessory suckers laterally situated, prominent and larger than the oral, acetabulum smaller than the oral sucker, placed in the region of the bifurcation of the œsophagus, hold-fast organ immediately behind it, nearly as large as the accessory suckers, circular or oval, with a longitudinal cavity, genital rudiments confined to the hind-body and recognizable as an oval, slightly lobed ovary to the outside of the cæcum, three lobes of testes, of which two are elongated and overlie the cæca and the third is oval and apposed to one of them, two branched excretory ducts on the inside aspect of the cæca unite posteriorly to open by a common terminal pore.

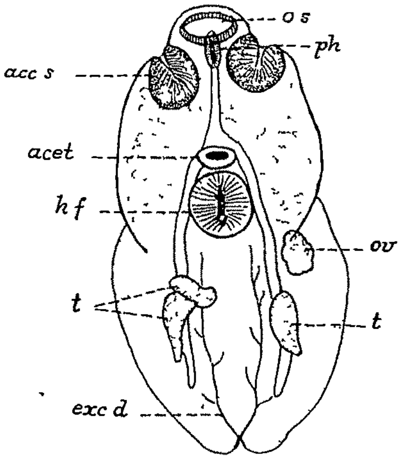

Fig. 1. Strigeid metacercaria from *Catla catla*. acc s, accessory sucker, acet, acetabulum, exc d, excretory duct, h f, hold-fast organ, ov, ovary, o s, oral sucker, ph, pharynx, t, testis

Among the several larval genera to which strigeid metacercariæ are attributed, *Diplostomulum* is one which possesses distinct accessory suckers, but it lacks a cyst-wall and inhabits mostly the eyes of fishes, though it may occur in other situations less often[1–3]. Black grub is caused by the genus *Neascus*[2,4], around which a host-cyst is developed. The metacercaria now described conforms to the morphological pattern of a *Neascus* in every aspect except for the possession of accessory suckers, and recalls the characters of the adult genus *Diplostomum* to a high degree.

To determine the identity of the adult worm, experimental infection of two ducks was attempted. Each bird was fed with live *Catla catla* having a heavy burden of metacercariæ, but no evidence of successful infection was obtained. Possibly other piscivorous birds like the egret and the snipe may prove susceptible.

It has been customary to recognize larval genera among Strigeids, and two of them—*Diplostomulum* and *Neascus*—have been referred to here as relevant, and it has been shown that the black grub of *Catla* does not correspond with either on all counts. But the similarity in structure between this one and the adult genus *Diplostomum* is emphasized to indicate the probable identity of the form.

This investigation is in progress as an item in the study of fish parasites, and a detailed account may be awaited We are grateful to Mr M Devidas Menon, assistant director of fisheries, Madras, for providing facilities, to Dr G Dubois, Neuchâtel, for valuable information, and to the Director of Industries and Commerce, and the Director of Animal Husbandry, Madras, for permission to publish these observations

Molecular Orientation in the Wings of a Termite

THE orientation of complex molecules in certain tissues is well known[1] I have recently observed that, although the main structure of the wing of a termite (*Macrotermes* sp) is isotropic, the two principal anterior veins (costal and sub-costal), running approximately parallel to the leading edge and to each other, show very marked anisotropy with the extinction direction parallel to the vein axis These brown veins appear to contain both chitin and sclerotin

X-ray photographs taken about the vein axis using copper K_α radiation lead to the idealized fibre diffraction patterns shown in Fig 1 (*a* and *b*) In both cases the rings are barely visible except very near the sickles The equatorial spacing of the untreated vein, Fig 1*a*, is 4 63 A, the meridional one is 3 48 A, with the sickles corresponding to not more than 7° disorientation These spacings could correspond either to fully extended β-keratin-type chains running in the direction of the vein axis (± 7°) with randomly orientated cross-linkages, or to orientated chitin molecules It seems likely that both these sources are contributing to the total diffraction pattern

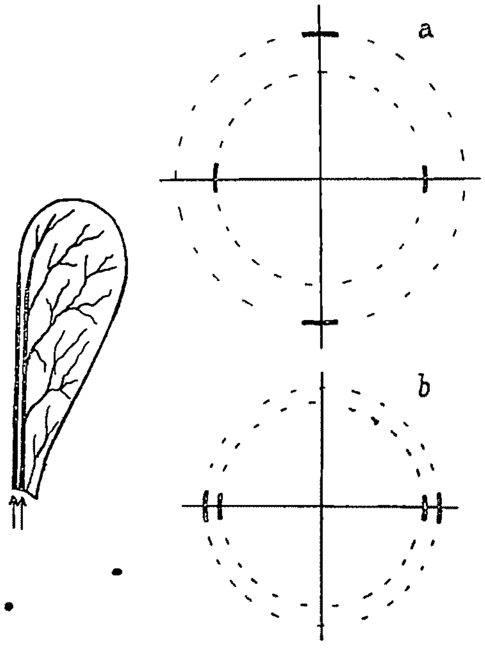

Fig 1 (*a*) Original fibres, (*b*) treated fibre Left principal veins on wing, indicated by arrows orientation corresponds to that of (*a*) and (*b*)

The veins may be cleaned and bleached by boiling them in concentrated potassium hydroxide for about twenty minutes. If the bleached vein is washed with ethanol and water and air-dried, the diffraction pattern of Fig 1*b* can be obtained This shows that the meridional spacing is no longer present, but that another equatorial spacing has appeared at 4 13 A, in addition to the former spacing at 4 63 A Hence the principal chain must be largely disintegrated by boiling with potassium hydroxide

Photoelectric Cell Observations of Insects in Flight

RECENT work in this Laboratory involved the exposure of a red-sensitive cæsium photoelectric cell to direct sunlight, the cell output being fed to a high-gain audio amplifier and a loud-speaker instead of the more usual d c. amplifier-galvanometer chain It was observed that occasional brief (< 0 25 sec) random 'bursts' of sound occurred, of apparent frequency between 100 c /s and 500 c /s. The number of 'bursts' in a given time varied considerably during the day, but appeared to rise to a peak in the late afternoon No moving object which might immediately explain the phenomenon was visible to the naked eye, and the sound produced was quite different from the continuous 'rumble' produced when tenuous cloud drifted across the sun's disk

The recording system was amended to use two photoelectric cells close together and feeding separate amplifiers. Observation of a number of 'bursts' showed that in many cases a burst recorded in one channel was followed after a discrete time-delay by a similar burst in the other channel This suggested moving objects as the cause, and from the geometry of the system and the duration of a burst, established their speed as of the order of 5–10 m p h and their range as relatively close.

Several of the bursts were recorded on magnetic tape and later played back, displayed on an oscilloscope, and their wave-forms photographed (p 129) Fig 1,*a* shows a typical burst of duration about 0 15–0 2 sec , and Fig. 1,*b* shows the same occurrence displayed on a faster sweep (150 m.sec.)

It is almost certain that these bursts of sound are caused by insects flying across the optical path between the sun's disk and the photoelectric cell, the generated frequency being due probably to the oscillation of the insect's wings, and the insects themselves being beyond the range of the unaided human eye or ear

Several different types of captive insect, for example, bee, common housefly, have been exposed in a transparent container to the photoelectric cell and their wave-forms obtained. Fig 1,*c* shows the wave-form produced by a bee fluttering its wings, photographed at approximately the same speed of sweep as was Fig 1,*b*. It will be seen that there is a close

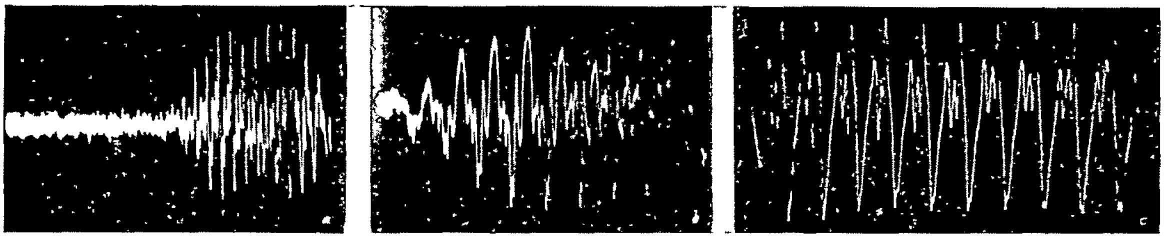

Fig 1

similarity. The fundamental period here is about 80 c /s , but the very high harmonic content makes the sound as recorded appear aurally much higher in pitch.

This phenomenon is reported here because it seems possible it might be turned to account by workers interested in the flight habits of insects, and particularly in variations in insect density during daylight hours

Optical Rotation and Polypeptide Chain Configuration in Proteins

Observations on the optical rotation of collagen and gelatin[1], together with consideration of polarimetric data reported in the literature for these and other proteins[2-6], have suggested the following simple hypotheses relating optical rotativity and polypeptide chain configuration

(1) Randomized chain configurations, provided by conditions which cause 'denaturation', exhibit rotations believed to correspond to the sums of effectively independent contributions of the L-amino-acid residues present. Values of $[\alpha]_D$ in the neighbourhood of − 100° characterize such states. For example, when native globular proteins are denatured by urea or similar reagents, the rotation invariably changes from an initially low negative value to about the range − 80° to − 120° [2-4]. Hot gelatin sols from various sources also show similar rotations[1,5,6]. Deviations within or near this range probably depend on variations (*a*) in completeness of denaturation, (*b*) in the amino-acid composition of the proteins involved, or (*c*) in minor aspects of the predominantly aqueous environments used for the measurements.

(2) The rotation in the native state appears to be the result of effects of specific main-chain configuration superimposed on or otherwise changing the optical rotation from that of independent, asymmetric α-carbon atoms alone. The resultant total rotation of the native protein may be appreciably greater or less than is obtained after denaturation Examples of the two possibilities are considered separately

(*a*) It is suggested that the very high negative rotations of native collagen solutions may result in large part from a helical configuration characteristic of the polypeptide main chains A citrate-soluble fraction of ichthycol (from the tunic of carp swim bladders) yielded[1] a specific rotation of − 350° under conditions which Gallop[7] has shown disperse the collagen as protofibrillar particles with mass per unit of (contour) length similar to that in normal condensed states (fibrils of connective tissues in general). Wide-angle X-ray diffraction studies have indicated that in these solid states there is helical structure along at least parts of the polypeptide chains[8]. Since the particulate cross-sections are not greatly altered during dispersion, it is reasonable to conclude that at least some of the helical configuration is retained in solution

As suggested by Robinson[5], a recovery of the native backbone configuration by gelatin upon cooling accounts for the high rotation of gelatin in gels and in films formed by evaporation in the cold. The latter also yield the characteristic infra-red absorption and wide-angle X-ray diagram of collagen Robinson described these phenomena in terms of a return of the specific 'collagen fold', which is here further described as helical. In comparable solution environments, however, the recovery seems to be incomplete, since gelatin does not fully regain the rotation of collagen[1]

(*b*) The specific rotations of native globular proteins are relatively low (− 30 to − 60°)[2,9]. Either (i) the main chain configuration is such as to oppose or to reduce the contributions of the α-carbon atoms weakly, or (ii) there are large cancelling effects resulting from enantiomorphic chain configurations The latter alternative becomes more likely if modern concepts of the importance of helical polypeptide chain configurations prevail, and if the case of collagen is taken as indicating that polypeptide helices should exhibit strong rotation. A complete cancellation of backbone effects need not result from a mixture of equal numbers of left- and right-handed helices composed of L-amino-acids, since one cannot assume that the contribution to rotation from the backbone dissymmetry is strictly additive with that due to the asymmetric α-carbon atoms.

(3) Since the pyrrolidine residues have special significance for main-chain structure, they may also be influential in determining optical rotation Helical configurations (including the α-helix) have no preferred sense of twist so long as imino-residues need not be incorporated frequently along the coil In fact, the occasional presence of such residues provides a means of turning corners or of producing a reversal of sense of twist[10] Thus, one might expect optically opposing chain configurations to occur in native globular proteins On the other hand, the uniquely high proportion of imino-residues in collagen provides a possible stereochemical reason for helices of one sense of twist, hence for large optical rotation, in that protein

An alternative explanation of the uniquely large rotation in collagen and cold gelatin, which seems less likely, is that the imino-residues may have unusually large rotations because of strains in the pyrrole ring, about the α-carbon, introduced when chains containing the pyrrolidines are impressed into the collagen configuration. In this case a specific rotation of − 350° for the protein would correspond to an estimated rotation of about − 1,200° for these residues

Finally, we may note that the comparisons made above have been based on rotations in the visible spectrum, in particular the sodium-*D* line, and that small differences in the rotatory dispersion bands, which are located in the ultra-violet for proteins, should not invalidate these generalizations The possible significance of the exact position of these absorption bands as an additional criterion for backbone configuration has recently been pointed out by Linderstrøm-Lang and Schellman[11]

This work was supported in part by a grant-in-aid, for the study of connective tissue structure, under the supervision of Prof. Richard S Bear, from the American Cancer Society upon recommendation of the Committee on Growth, National Research Council I thank Prof Bear for advice and encouragement, as well as Dr Alfred Gierer for helpful discussions This report is based on part of a Ph D thesis submitted to the Massachusetts Institute of Technology, June 1954

Gamma-Rays from Proton Bombardment of Sodium

THE yield of the (p,γ) capture process in sodium-23 has been studied for proton energies ranging between 0 5 and 1 0 MeV

Thin vacuum-evaporated sodium iodide and thick sodium sulphate targets were bombarded with protons from the van de Graaff generator The magnetic field of the analysing magnet was measured by means of a proton resonance fluxmeter As a detector for the γ-rays a sodium iodide (tantalum) crystal was used Calibration was achieved by means of the 873 5 ± 0 8 keV. resonance in the $^{19}F(p,\alpha\gamma)^{16}O$ reaction[1].

* Misprinted as 576 in Burling's paper

In Table 1 the resonances are listed and compared with the results of other authors[2]. The resonance near 874 keV is in some papers supposed to be due to fluorine contamination It has been shown recently[3], however, that there is also a sodium resonance close to that energy The fluorine contamination in our targets was found to be less than one part in 500,000

Paramagnetic Resonance in Copper Phthalocyanine

PARAMAGNETIC resonance measurements on copper phthalocyanine are of considerable interest for two reasons First, the central structure of the phthalocyanine molecule is similar to that of hæmoglobin and chlorophyll[1], and hence any detailed information that can be derived on the electronic binding will be of great biophysical importance Secondly, the copper atom is surrounded by four nitrogen atoms, and not water molecules, as in nearly all the copper salts previously studied by paramagnetic resonance It was therefore expected that the observed *g* factors and hyperfine splittings might be somewhat different from the usual values[2], and this has been confirmed, the hyperfine splitting along the field axis being nearly twice as great as the maximum values previously reported

Initial measurements on concentrated crystals have been briefly reported before[3] , but it has now proved possible to observe signals from diluted crystals, and thus resolve the hyperfine structure, and study its angular variation. It can be seen from the results summarized below that a considerable amount of data is now available for calculations on the copper–nitrogen bonding. Since the crystal size is limited to about 0 5 mm [3], all the measurements have been made at either 1 25 cm. or 8 mm wavelengths, and temperatures down to 20° K have been employed to increase the sensitivity The hyperfine splittings and *g* values were all measured by means of a proton resonance magnetic field meter, and good signals were obtained from coils of 2 mm diameter, which enabled simultaneous measurement of the proton and electron resonance in all cases

Detailed X-ray analysis is available for the metal phthalocyanines[4], and the orientation of the planar molecules with respect to the crystalline axes is known accurately It is therefore possible to correlate all the paramagnetic resonance measurements with the actual directions of the copper–nitrogen bonds The central structure of the copper phthalocyanine consists of a square, formed by four nitrogen atoms, with the copper atom at the centre, coplanar with the rest of the molecule There are two molecules per unit cell, and hence two spectra are usually observed The magnetic field was rotated around the crystal, in the '*ab*', '*bc*' and '*ca*' planes, and then in, and perpendicular to, the plane of the molecules

The diluted crystals show four hyperfine components, due to the $I = \frac{3}{2}$ of ^{63}Cu and ^{65}Cu With present sensitivity the line-width cannot be reduced much below 50 gauss, and so far no fine structure, due to any covalent linkage with the nitrogen atoms, has been observed The maximum splitting between successive hyperfine components is 210 ± 10 gauss, and the maximum g value is 2 165 ± 0 004, both occurring along the axis through the copper atom normal to the plane of the four nitrogens In the plane perpendicular to this axis, that is, the plane of the molecule, the g-value remains isotropic at 2 045 ± 0 003 The hyperfine splitting in this plane collapses to an ill-resolved pattern, as is usual in copper salts, having an approximate value of B = 30 ± 10 gauss. However, there does seem to be a 180° variation of this splitting for rotation in the plane of the molecule The difference is small but appears to be outside the experimental error, and is being studied more closely, as it may give information which differentiates the individual copper–nitrogen bonds

The same g values and hyperfine splittings are obtained at both 1 25 cm and 8 mm wave-lengths, and also over a temperature-range of 20°–290° K They can be summarized in terms of the normal spin Hamiltonian coefficients as

$$\begin{array}{llll} g_{\shortparallel} = 2\ 165 \pm 0\ 004, & g_{\perp} = 2\ 045 \pm 0\ 003 \\ A = 0\ 0208 \pm 0\ 001\ \text{cm}^{-1}, & B = 0\ 0031 \pm 0\ 001\ \text{cm}^{-1} \end{array}$$

The quadrupole interaction coefficient, Q, has not been calculated yet, as more sensitive apparatus is being constructed to allow greater dilution and better resolution It is then hoped to carry out a detailed study of the hyperfine splitting in the molecular plane, and also search for any interaction of the electrons with the nitrogen nuclei.

This work forms part of a general programme for studying phthalocyanine, hæmoglobin and chlorophyll derivatives by paramagnetic resonance We would like to thank the Royal Society for a grant towards the cost of the apparatus, Imperial Chemical Industries, Ltd, and Dr C E Dent for supplying phthalocyanines, Dr Stevens for much helpful discussion, and the Department of Scientific and Industrial Research for a maintenance grant (J E B)

Fixation in Electron Microscopy

Many specimens for electron microscopical examination are in the form of suspensions in salt solution These are commonly dried on the specimen support film, and the unwanted salt crystals are removed by washing, with resultant uncertainties due to loss of material during the process, which losses may well be selective The salts are sometimes first removed from the suspensions by dialysis, but this may lead to changes in aggregation, or to loss by precipitation before the material can be finally laid down

These difficulties have been largely overcome here by working on a micro scale and using the mounting film itself as the dialysis membrane The film is floated off a glass support on to a water surface in the usual way, and a single drop (or sometimes a spray of micro-drops) is placed on top of the film. The salts diffuse through the film very rapidly as it is usually only 300 A thick, and the specimen is then mounted in the normal manner

Further, it is often desirable to fix such specimens without change of electrolyte balance in the process This is now readily achieved by placing drops of the suspension on a mounting film floating on a bath of the suspending medium, which contains the fixative in addition to the normal concentration of salts. Fixation proceeds gradually by diffusion of the agent through the film and the bottom of the drops, or in the vapour phase through the top of the drops, without change in electrolyte balance Removal of unused fixative and unwanted salts is accomplished by transferring the film to a water surface as before The concentration of the fixative gradually rises in the drops from zero to that of the main bath Such progressive fixation has been shown to be most desirable, and the dangers inherent in adding concentrated fixative to the suspension itself are avoided

Similarly, other micro-chemical modifications of the specimen material may be carried out without fear of selective loss by precipitation and consequent rejection prior to normal mounting procedures, since the insoluble contents of the original drops necessarily remain on the mounting film

The method has been used to advantage over the past two years in studies of tumour and normal tissue extracts, isolated cell components (lipid fraction, mitochondria, microsomes), bacteriophage behaviour at various pH-levels (precisely controlled by working with standard buffer solutions) and the organisms of pleuro-pneumonia and related materials

Allotropes of Tungsten

The element tungsten has been observed to exist in two structural forms the commonly encountered modification, which is body-centred cubic with a = 3 16 A, and another which has a more complex cubic structure with 21 atoms per unit cell and a = 5 04 A These forms have been designated α and β respectively by Hartmann, Ebert and Bretschneider[1], who first reported the existence of the β-form, and this nomenclature is commonly accepted, although Neuberger[2] reverses the designations

Hartmann and others have shown that the β-form is stable below c 650° C, above which temperature it is irreversibly converted to α-tungsten, the transition being relatively sluggish No reports have yet been published that α-tungsten can be reconverted to β-tungsten by purely physical processes, so that it has only been obtained hitherto by winning the element at temperatures below the transition temperature Metallic tungsten prepared at these temperatures is, however, only obtained in the β-form by the decomposition of certain of its compounds

In this laboratory, tungsten has been prepared by several different methods and the product has been examined by X-ray diffraction The results obtained are tabulated below, together with others taken from the literature

Method of preparation	Temperature (° C)	β-Tungsten present
Hydrogen reduction of β-oxide ($W_{20}O_{58}$)	465–720	+
Hydrogen reduction of γ-oxide ($W_{18}O_{49}$)	470–660	+
Hydrogen reduction of δ-oxide (WO_2)	550–590	—
Hydrogen reduction of WCl_6 vapour	c 430	—
Hydrogen reduction of $WOCl_4$ vapour	c 430	—
Electrolysis of fused melts containing tungstates or WO_3	600	+
Electrolysis of fused melts free from oxides	450–550	—
By an oxidation reduction cycle*	600	+
	700	—
Electrolysis of phosphate containing WO_3 (ref 1)	600–750	+
Electrolysis of tungstates (ref 3)	500	+
Hydrogen reduction of WO_3 (ref 4)	up to 800	+
Films of tungsten developed on the envelopes of lamps (ref 4)	—	+
Sputtered films (ref 5)	—	+
On tungsten electrodes of spark gap (ref 5)	—	+

* The oxidation-reduction cycle involves the transfer of metal from a tungsten filament, held at c 2,000° C in wet hydrogen, on to a nearby surface which was maintained at the temperature given in the table

It should be noted that β-tungsten may be detected in metal formed at temperatures above the transition temperature, and this fact confirms the slowness of the β–α conversion

We conclude that β-tungsten can only be formed by chemical processes, and then only when certain oxides are present or likely to be formed in the system Our findings, and evidence from other work in this laboratory, appear to offer additional support for the proposal by Hagg and Schonberg[6] that the β-form is, in reality, an oxide of tungsten Work is continuing on this subject, and we hope to publish a more complete report later

We wish to thank Mr M G Harwood, who was responsible for the X-ray diffraction examination of samples, and Mr J A M van Moll and the directors of Philips Electrical, Ltd , for permission to publish these results

Fine Structure of Solar Radio Transients

The impending rise of solar activity makes it appropriate to discuss some observations which have been only reported upon orally[1] and mentioned in the popular press[2]. At 480, 160 and 51 Mc /s a study was made of progressive disturbances in the solar atmosphere[3] using high-speed recordings with fast instruments Solar bursts were found to be composed of a great number of small transients or discrete pips Each pip had a steep but not impulsiv rise, an approximately half-sinusoidal top, at first rapid decay and a quasi-logarithmic tail Its duration was taken as the elapsed time, to the neares tenth of a second, between points at 0 707 of maximum amplitude Plots were made of duration versu amplitude which turned out to be scatter diagrams Ninety per cent of the durations fell between two thirds and three halves of the median, and wer independent of amplitude throughout a range o more than one to a hundred These limits represen the smallest pips observed on a quiet day and th largest separate pips during an outburst Th median durations were respectively 0 7, 2 and 6 sec Thus the duration of a pip in seconds is approximately equal to its observed wave-length in metres, o $T = \lambda$ Obviously the many overlapping pips in solar burst are the result of many discrete source acting independently Periods of high-variabl background are merely a great number of pips o nearly the same amplitude and random timing

No correlation could be found between any o the fine structure at 160 and 205 Mc /s , so the band width of a pip must be much narrower At 15 and 160 Mc /s large pips on one trace could alway be found in counterpart on the other trace Abou one in a hundred of the large pips had amplitude equal within 2 per cent Approximately one-fift had amplitudes equal within 10 per cent As weake pips were considered, the correlation became poorer Small wiggles were entirely random and probabl represent the spectral tails of pips at far-remove frequencies Obviously the spectral width of a pi is only a few per cent of its mean frequency. Visua inspection indicated that the pips of medium amplitude were often of more nearly equal amplitude tha the very strong pips Thus an inverse relationshi may exist between spectral-width and amplitude. Th frequency of occurrence of the pips was greatest a 160 Mc /s , but the mean amplitude increased in direct way with wave-length

A few suitable recordings were made by Cornel on 1,420 Mc /s which showed some small pips wit durations of a couple of tenths of a second Publishe data[4] at 19 Mc./s show pips about a quarter of minute long. During the greatest sunspots of 194 and 1947, surges with durations from a half to on minute were observed[5] down to 6 7 Mc /s. All thes observations provide evidence that the relatio $T = \lambda$ holds approximately over a range of severa hundred to one in wave-length Some of the low frequency data[6] confirm that the spectral width i small, such as November 18, 1948, 0135 G M T peak noise 8,330 kc /s., limited to 8,270–8,400 kc /s.

Apparently, there is a fundamental relatio between the mode of generation of these transients the location of the source in the solar atmospher and the duration of a pip These observations wer made by me during 1948–50 while associated with th National Bureau of Standards

* Values for the test when disk with hole 4 mm diam was used The data shown in columns 5 and 10 indicate the relative strengths f the membranes The membrane was supported on a brass disk of thickness 2 mm having a central circular hole of diameter 4 mm or 8 mm he disk with membrane surmounted by a rubber washer was placed in a special adaptor which was clamped to the top half of an Elford ultralter (ref 6) by means of a hexagonal nut Pressure was applied to the system and increased slowly until the membrane was ruptured The inimum pressure required to break the membrane is recorded in column 5 or 10 The rate of flow of water (*RFW*), specific water content WC) and average pore diameter (*APD*) were determined by the methods described by Elford and Ferry (ref 7)

Brown[1] has graded collodion membranes, after oagulation in water, by immersing them in mixtures f ethyl alcohol and water in varying proportions nsuccessful attempts were made in this laboratory o swell dried 'Gradocol' membranes by similar ethods using various alcohols

'Gradocol' membranes of porosities ranging from mμ to 2,000 mμ were dried by treatment with either thyl, *n*-propyl, *iso*propyl, *n*-butyl, *iso*butyl or amyl lcohol, followed by either chloroform, carbon tetrahloride, dichlorethylene, benzene or petroleum ether. or the whole range of porosities, only *iso*butyl or myl alcohol could be used successfully in combinaion with petroleum ether (preferably of boiling point 0–60° C) for drying the membranes without impairent to their characteristics (Table 2) (cf. Grabar[2])

The membrane to be dried (4 0 cm or 5 6 cm. in iameter, weighing 0 05–0 1 gm) was placed between olds of filter paper to remove superficial water, and hen immersed in 50 ml *iso*butyl or amyl alcohol t was transferred twice to approximately 50 ml fresh lcohol in separate closed vessels for 5–10 min ntervals Then the superficial alcohol was removed ith filter paper and the membrane washed three imes with petroleum ether in a similar manner The embrane was dried at room temperature or 60° C.

Collodion particles used for adsorption studies were obtained, either by the Loeb method[3] or by grinding under water in a ball-mill thin strips of those normally discarded portions of 'Gradocol' membranes prepared by the Elford technique[4]. The nitrocellulose particles prepared by the latter method were graded, when dry, by passage through a No 100 B S S sieve. They were then shaken with water in a stoppered cylinder and separated from finer particles by decantation This process was repeated until the supernatant was clear The collodion particles were activated by the method described by Sollner, Abrams and Carr[5].

Membranes or nitrocellulose particles treated by the method described above may be stored or transported in the dry state The membranes may be marked with Indian ink and stored in the dark for many months in paper envelopes or glass vessels together with others of different porosity When re-equilibrated against water, their characteristics remain unchanged from the original, that is, thickness, rate of flow of water, mechanical strength, specific water content and porosity remain unaltered (see Table 2)

Such dried membranes of predetermined characteristics may be sealed, by means of a 5 per cent solution of nitrocellulose shreds in ether alcohol (1 1) mixture, to the end of a narrow tube to make a filter stick or a wide tube (for example, a Gooch crucible adaptor) for use in dialysis.

Chromatography and Paper Electrophoresis of Sulphonphthalein Dyes

Two of the sulphonphthalein dyes, bromophenol blue[1] and bromocresol green[2], have been used widely for the detection of protein after electrophoresis on filter paper The uptake of bromocresol green by protein under these conditions has been studied recently by Franglen and Martin[3] Extending this work, the purity of other sulphonphthalein dyes has been investigated with paper chromatography and filter paper electrophoresis , the methods used and the results obtained are described below.

The dyes examined are listed in Tables 1 and 2, and were supplied by the British Drug Houses, Ltd , as a grade suitable for *p*H determination These were made up as 2 per cent (w/v) solutions in absolute ethanol , all the dyes went completely into solution

The positions of the dyes after chromatography or electrophoresis were determined by inspection under normal light, and under ultra-violet light of 2537 A given by a Hanovia 'Chromatolite' Under ultra-violet light, bright fluorescence was observed in all the dyes except in those containing substituted *m*-cresol rings , these, in contrast, were markedly absorbent

For chromatographic analysis, the solutions were applied as 20-µl spots by an 'Agla' microsyringe to sheets of Whatman's filter paper No 3 *MM* A number of different developing systems were tried , the following pair were found to be the most satisfactory In the first, the paper was equilibrated over-night with purified *tert* -amyl alcohol and concentrated ammonia solution (spec. grav 0 880), and was developed by descending chromatography with the following mixture purified *tert* -amyl alcohol, 200 ml , and concentrated ammonia solution (analytical reagent grade, spec grav 0 880), 50 ml The chromatogram was run for 26 hr , during which the front advanced about 31 cm past the original positions of the spots In the second set of conditions, the paper was equilibrated over-night with purified *tert* -amyl alcohol, glacial acetic acid and water, and was developed with a solution containing purified *tert* -amyl alcohol, 200 ml , glacial acetic acid (analytical reagent grade), 50 ml , and distilled water, 50 ml The chromatogram was run for 26 hr , during which the front advanced about 34 cm past the original positions of the spots

The results are shown in Table 1, in which the R_F of each main component is noted, together with the number of other components detected In most of the dyes, these other components are present small quantities, the majority of them being detec only by their fluorescence under ultra-violet lig In the case of chlorophenol red, however, the se other components form a large part of the sam and four of them are clearly visible on the chroma gram under normal light One of the compone separated from the chlorophenol red sample appea to be identical with bromophenol blue, both chromatography in the two different develop systems described and by paper electrophoresis

Table 1 CHROMATOGRAPHIC ANALYSIS OF SULPHONPHTHALEIN DYES ON WHATMAN'S NO 3 *MM* FILTER PAPER

Dye	Developing system			
	Amyl alcohol – ammonia		Amyl alcohol – acetic acid	
	R_F of main component	No of other components	R_F of main component	No of other components
Bromophenol blue	0 27	1	0 74	0
Bromocresol green	0 32	1	0 79	0
Chlorophenol red	0 09	6	0 67	6
Bromophenol red	0 11	4	0 68	5
Bromocresol purple	0 19	2	0 76	5
Bromothymol blue	0 50	0	0 88	0
Phenol red	0 06	4	0 54	3
Cresol red	0 12	4	0 67	3
Metacresol purple	0 16	3	0 66	2
Thymol blue	0 70	0	0 85	0

Table 2 ELECTROPHORETIC ANALYSIS OF SULPHONPHTHALEIN DYE WHATMAN'S NO 4 FILTER PAPER IN 0 06 *M* DIETHYLBARBITU BUFFER, *p*H 8 6

Dye	Mobility of main component (cm^2/V sec × 10^5)	No of other components
Bromophenol blue	12 8	0
Bromocresol green	13 5	0
Chlorophenol red	14 4	3
Bromophenol red	13 8	1
Bromocresol purple	13 4	2
Bromothymol blue	11 9	0
Phenol red	13 8	3
Cresol red	12 2	3
Metacresol purple	12 2	0
Thymol blue	9 0	0

In both chromatographic systems, all the co ponents formed compact spots, except those bromophenol blue and the 'bromophenol blue' s in the chlorophenol red sample In the latter cas pronounced tailing occurred in the amyl alcoh ammonia run Earlier observations suggest that t tailing is due to a gradual and irreversible breakdo of bromophenol blue in alkaline conditions[3] breakdown was observed in any of the other dyes either of the systems

For electrophoretic analysis, the dye solutic were applied as 5-µl spots to a sheet of Whatma No 4 filter paper. Electrophoresis was carried in an apparatus similar to that described by Frangle using 0 06 *M* diethylbarbiturate buffer, *p*H 8 6, a applying a potential difference of 8 0 V /cm 3 hr

The results of electrophoresis are shown in Table In calculating the rates of migration of the dy endoelectrosmosis has been taken into account T was determined from the movement of a spot dextran solution included in the run[4]

These analyses show that sulphonphthalein d can be readily distinguished from each other filter-paper techniques Chromatography was fou to be more effective in most cases than electrophores the latter method, however, enables bromophe red to be separated from cresol red It is also appar from these analyses that the majority of the samp tested have appreciable quantities of impurities T may prove to be of importance in their use for t semi-quantitative determination of *p*H

I wish to thank Prof N. H Martin for his enco agement during this work, and to acknowledge t financial help given by the Research Fund of George's Hospital

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, January 17

Society of Chemical Industry (joint meeting of the **Agriculture** nd **Pesticides Groups**, at the Chemical Society, Burlington House, ccadilly, London, W 1), at 5 30 p m —Mr J T Martin and Mr V Coles "The Analysis of Insecticides—Tar Oils and Summer ls", Mr K Gardner "The Analysis of Weedkillers—MCPA and noseb"

University of London (in the Anatomy Theatre, University llege, Gower Street, London, W C 1), at 5 30 p m —Prof W H cisz (University of Groningen) "Problems of Transport in Plants" urther Lectures on January 19 and 21)*

Institute of Metal Finishing (at the Northampton Polytechnic, John Street, London, E C 1), at 6 15 p m —Mr V F Henley ome Aspects of Sulphuric Acid Anodising to Specification D T D 0C"

Pharmaceutical Society of Great Britain (at 17 Bloomsbury quare, London, W C 1), at 7 30 p m —Dr Douglas McKie "The igins of Chemistry—Alchemy or Technology ?"

Tuesday, January 18

University College, London (in the Anatomy Theatre, Gower treet, London, W C 1), at 1 15 p m —Prof J Z Young, F R S The Counting of Microscopic Particles" *

Institute of Physics, Electronics Group (at 47 Belgrave quare, London, S W 1), at 5 30 p m —Dr R F Saxe "Millimicroecond Techniques"

Institution of Chemical Engineers (at the Geological Society, urlington House, Piccadilly, London, W 1) at 5 30 p m —Mr R C Pratt and Mr J A McWilliams "Performance Data for xpanded Metal Column Packing", Mr F Knelmann, Mr N ombrowski and Prof D M Newitt "The Mechanism of Drop ormation from Gas or Vapour Bubbles"

Institution of Electrical Engineers, Measurements Section t Savoy Place, London, W C 2), at 5 30 p m —Discussion on "The uman Operator in Closed Loop Control Systems"

Society of Chemical Industry, Agriculture Group (at the hemical Society, Burlington House, Piccadilly, London, W 1), at 30 p m —Dr C Bloomfield "Leaf Leachates as a Factor in edogenesis"

Scientific Film Association (in the Shell Film Theatre, Shellex House, Strand, London, W C 2), at 6 30 p m —Mr Trevor letcher "Cinemathematics"

Society for Analytical Chemistry, Physical Methods Group t the Iron and Steel Institute, 4 Grosvenor Gardens, London, S W 1), t 6 30 p m —Papers on "Solvent Extraction"

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), t 7 p m —Dr E G West "Manufacture of Integral Structures"

Wednesday, January 19

Royal Society of Arts (at John Adam Street, Adelphi, London, C 2), at 2 30 p m —Dr W Idris Jones "Research in the Coal ndustry" (Cadman Memorial Lecture)

Royal Meteorological Society (at 49 Cromwell Road, South ensington, London, S W 7), at 5 p m —Discussion meeting on "Airow Over Mountains" *

Royal Statistical Society (at the London School of Hygiene nd Tropical Medicine, Keppel Street, London, W C 1), at 5 15 p m —Mr Philip Redfern "Net Investment in Fixed Assets in the nited Kingdom, 1938–1953"

Eugenics Society (at the Royal Society, Burlington House, iccadilly, London, W 1), at 5 30 p m —Prof L S Penrose, F R S The Genetics of Microcythaemia (Thalassaemia)" *

Institution of Electrical Engineers, Education Discussion ircle (at Savoy Place, London, W C 2), at 6 p m —Discussion on Education and Training for Engineers and Craftsmen in France"

Royal Institute of Chemistry (joint meeting with the **London ection** of the **Society of Chemical Industry**, in the Chemistry ecture Theatre, King's College, Strand, London, W C 2), at 6 30 p m —Prof M Stacey, F R S "Some Recent Advances in Organic hemistry"

Thursday, January 20

Bone and Tooth Society (at the Institute of Orthopædics, 234 reat Portland Street, London, W 1), at 5 p m —Symposium on Fluorosis"

Linnean Society of London (at Burlington House, Piccadilly, ondon, W 1), at 5 p m —Miss D J Jackson "The Capacity for light of Water Beetles, with Observations on Various Species ccurring in the Western Scottish Isles", Dr W A Clark "Plant istribution in the Western Isles"

Institute of Fuel (at the Institution of Civil Engineers, Great eorge Street, London, S W 1), at 5 30 p m —Discussion on "The eaver Report of the Committee on Air Pollution" *

University College, London (in the Electrical Engineering heatre, Gower Street, London, W C 1), at 5 30 p m —Prof F Brailsord "The Domain Theory of Ferromagnetism" (Further Lectures n January 27 and February 3)*

Institute of Physics, Education Group (at 47 Belgrave Square, ondon, S W 1), at 6 p m —Prof Norman Ramsey "The Training f Physicists in the United States of America"

Society of Chemical Industry, Road and Building Materials Group (in the Lecture Hall of the Institution of Structural Engineers, 11 Upper Belgrave Street, London S W 1), at 6 p m —Mr Y W Rayden "Plastics in the Building Industry"

Chemical Society (in the Large Chemistry Lecture Theatre, Imperial College of Science and Technology, South Kensington, London, S W 7), at 7 30 p m —Prof H C Longuet-Higgins "The Role of the π-Electron in Aromatic Chemistry" (Tilden Lecture)

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W 1), at 7 30 p m —Symposium on "Loiasis"

British Institute of Radiology, incorporated with the **Rontgen Society** (in the Reid-Knox Hall, 32 Welbeck Street, London, W 1), at 7 45 p m —Special General Meeting, followed by Scientific Papers

British Psychological Society, Social Psychology Section (in the Eugenics Theatre, University College, Gower Street, London W C 1) at 8 15 p m —Prof T H Pear "Etiquette, Manners and Good Will"

Friday, January 21

Society of Chemical Industry Corrosion Group (in the Great Hall of Battersea Polytechnic, Battersea Park Road, London, S W 11), at 10 a m —Exhibition—"Corrosion Prevention in the Home" *

Royal Geographical Society (joint meeting with the **Institute of Navigation**, at 1 Kensington Gore, London, S W 7), at 5 p m —Mr Frank Evans "Transatlantic Drift"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Scientific Officer, Grade 1 (with a university degree of high standard in physics or equivalent qualifications, and preferably with some experience in optical instrumentation), **in the Instrumentation Section** of the Aeronautical Research Laboratories (Department of Supply—High Speed Aerodynamics Division), Salisbury, South Australia, for the development and design of general physical and particularly optical instruments for aerodynamics research—Senior Representative (A P 23), Department of Supply, Australia House, Strand, London, W C 2 (January 20)

Analytical Chemist (with an appropriate degree or Associate of the Royal Institute of Chemistry, and preferably with some experience in an industrial laboratory) in the Central Laboratory—Chief Personnel Officer, North Western Gas Board (Liverpool Group), Radiant House, Bold Street, Liverpool 1 (January 24)

Agronomist, Grade 3 (with a degree in agriculture or equivalent qualifications, and experience in agronomic research and commercial rubber planting), in the Public Service of the Territory of Papua and New Guinea—The Official Secretary, Australia House, The Strand, London, W C 2 (January 31)

George Angus Student (graduate of an approved university or holder of approved qualifications) for postgraduate research in the Department of either Chemistry, Physics or Mechanical Engineering—The Registrar, King's College, Newcastle-upon-Tyne (January 31)

Lecturer in Animal Nutrition in the Department of Veterinary Hygiene and Animal Husbandry—Secretary, Royal Veterinary College, Royal College Street, London, N W 1 (January 31)

Research Officer (with an honours degree in science with botany and chemistry as major subjects, or in agricultural science or equivalent qualifications) **in the Plants and Soils Laboratory**, Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization, Brisbane, Queensland, to undertake studies on the factors limiting legume establishment in the sub-tropical areas and Southern Queensland—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2, quoting 146/34 (February 5)

Senior Lecturer in Physics, and a **Lecturer in Mathematics**, at Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W C 1 (February 7)

Reader in Electrical Engineering at the University of Adelaide, Adelaide, South Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (Adelaide, February 14)

Lecturers in Engineering—The Registrar, The University, Manchester 13 (February 15)

Lecturer or **Assistant Lecturer** (with special interests in genetics or genecology) **in Botany**—The Registrar, The University, Leeds 2 (February 19)

Assistant (with a degree in agriculture or equivalent qualifications and preferably at least two years postgraduate experience) **in the Agricultural Section**—The Director, Tea Research Institute of East Africa, P O Box 91, Kericho, Kenya Colony (February 28)

Head (with high qualifications in geology and experience in both teaching and research) **of the Department of Geology**—The Principal, Chelsea Polytechnic Manresa Road, London, S W 3 (February 28)

University Lecturer, and **University Demonstrators** (2) **in Chemical Engineering**—The Appointments Committee of the Department of Chemical Engineering, Tennis Court Road, Cambridge (March 11)

Research Officer (with at least an honours degree in metallurgy or metallurgical engineering, or equivalent qualifications) **in the Mechanical Engineering Research Laboratory**, South African Council for Scientific and Industrial Research, Pretoria, for research work in the field of ferrous and non-ferrous physical metallurgy—South African Scientific Liaison Officer, Africa House, Kingsway, London, W C 2 (Pretoria, March 15)

I C I Research Fellows in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology, Physics or allied subjects—The Academic Registrar, University of London, Senate House, London, W C 1 (April 16)

Turner and Newall Research Fellows in Engineering, Inorganic Chemistry, Physics or an allied subject—The Academic Registrar, University of London, Senate House, London, W C 1 (April 16)

Aerodynamicists and Aeronautical Engineers, Scientific Officer grade (with a first- or second-class honours degree in engineering, physics or mathematics, and preferably with some research or experimental experience of aircraft problems) at the Ministry of Supply Aeroplane and Armament Establishment, Amesbury, Wilts, National Gas Turbine Establishment, near Farnborough, Hants, Royal Aircraft Establishment, Farnborough, Hants, and at London H Q—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1, quoting A 354/54A

Agricultural Education Officer (with a degree in agriculture and experience in teaching), in Basutoland, to take administrative and academic charge of a new training centre for subordinate staff of the Agricultural Department—The Director of Recruitment, Colonial Office, Great Smith Street, London, S W 1, quoting BCD 63/76/07

Assistant Professor (with a special interest in low temperature research) in the Department of Physics—Prof W H Watson, University of Toronto, Toronto, Canada

Associate Professor of Physics—The President, Memorial University of Newfoundland, St John's, Newfoundland, Canada

Chemist, Experimental Officer grade (preferably with experience of analytical work in any field), in the Department of Insecticides and Fungicides, for general analytical work and assisting in developing analytical methods for determining insecticides in soil and in plant materials—The Secretary, Rothamsted Experimental Station, Harpenden, Herts

Chemist (with a degree in natural science, and preferably postgraduate experience, particularly in soil survey work) in the Agricultural Department, Sierra Leone, to make a soil survey of part of the Northern Province of Sierra Leone, with particular reference to the nutrient status and fertilizer requirements of soils suitable for mechanized rice cultivation—The Director of Recruitment, Colonial Office, Great Smith Street London, S W 1, quoting CDE 63/15/04

Chemists (with at least H N C in chemistry or equivalent qualifications) to develop and apply methods of analysing biological and other materials for very low levels of radioactivity—Establishments Officer, United Kingdom Atomic Energy Authority, Atomic Energy Research Establishment, Harwell Didcot, Berks, quoting 2/103/217

Experimental Officer or Assistant Experimental Officer (with at least H S C (science) or equivalent and preferably with some experience in the handling of explosives together with some knowledge of electronics), at Fort Halstead, Kent, to perform experimental physical research using small explosive charges and high-speed recording equipment—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 146/WGE/2

Lecturer (with experience in wind tunnel research work) in the Department of Aerodynamics—The Recorder, College of Aeronautics, Cranfield, Bletchley, Bucks

Plant Pathologist (graduate in pure or applied botany) in the Hop Research Department—The Registrar, Wye College, Wye, Kent

Research Assistant (preferably with previous experience in metallurgical analysis) to assist in experimental work connected with the chemistry of steel making, and to carry out analysis of metals and slags—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W 1, quoting "Analysis"

Scientific Officer (with a first- or second-class honours degree in physics or electrical engineering, or equivalent qualifications), at the R A F Station, near High Wycombe, Bucks, for operational research duties, theoretical studies and development work in the field of communications and general electronics—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1, quoting A 109/54A

Scientific Officer (with a degree in chemistry or equivalent), at the Ministry of Agriculture and Fisheries, Tolworth, Surrey, for general chemical and analytical work connected with chemical methods for the control of various animal pests and insects on stored products—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1, quoting F 679/54A

Senior Experimental Officer (preferably with a pass degree in chemistry, and previous experience of the control of staff and of work on explosives) to advise technical and scientific staff on safe working in laboratories, pilot plant, and production units associated with a wide range of chemical and physical research problems—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks quoting 336/WGE/2

Technical Assistants (with Inter B Sc or equivalent qualification) at the Central Laboratory, Chiswick—The Staff Officer (F/EV 519) London Transport, 55 Broadway, London, S W 1

Technician (with a sound knowledge of routine hæmatology procedures)—The Secretary, The Laboratory, Peace Memorial Hospital, Watford, Herts

Technician (with experience in the main branches of histological technique and also in photomicrography) in the Histology Laboratory—The Registrar, The University, Bristol 8

Electrolyte Solutions

By R A ROBINSON, D Sc, Ph D, F R I C, Professor of Chemistry, University of Malaya, Singapore, and R H STOKES, Ph D, D Sc, F R A C I, A R I C, Reader in Physical Chemistry, University of Western Australia

A detailed account of the present state of knowledge of some of the most fundamental properties of electrolytes, conductance, chemical potential and diffusion, from the standpoint of the practical electrochemist

Modern experimental methods are discussed at some length, and extensive results are given, together with numerous tables useful in computations on electrolyte solutions

Price 56*s*

Chemisorption

By B M W TRAPNELL, M A, Ph D, Lecturer in Chemistry, University of Liverpool

This book is designed to give a balanced presentation of the subject of chemisorption, in particular of discoveries made over the last fifteen years, but hitherto only available as original papers scattered over many journals The main aspects of the subject are discussed, but the treatment is selective in that the author has concentrated on those features which are best understood in our present state of knowledge

The main part of the book, concerned with chemisorption itself, treats velocities of adsorption and desorption, equilibrium at surfaces, heats and mechanisms of adsorption, and the mobility of adsorbed layers Then since chemisorption is also of interest to chemists in its relationship to heterogeneous catalysis, the two final chapters show how studies of the former can contribute to understanding of the latter In these chapters the causes of catalytic specificity are discussed, together with the mechanisms of some simple catalytic reactions, including olefine hydrogenation and the cracking of hydrocarbons

LECTURES AND COURSES

UNIVERSITY OF LONDON

A course of three lectures on "Approximate Solution of Boundary Value Problems in Mathematical Physics by the Method of the Hypercircle in Function-Space" will be given by Professor W Prager (Brown University) at 5 30 p m on January 24, 27 and 28 at King's College Strand W C 2

Admission free, without ticket

JAMES HENDERSON,
Academic Registrar

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 *to* 64 *inclusive, or a woman aged* 18 *to* 59 *inclusive unless he or she, or the employment is excepted from the provisions of the Notification of Vacancies Order,* 1952

SOUTH AFRICAN COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

METALLURGIST RESEARCH OFFICER

Applications are invited for a post as Research Officer in the Mechanical Engineering Research Laboratory of the C S I R, Pretoria South Africa The salary scale associated with this post is £780 by £48 to £1 020 per annum In addition a cost-of-living allowance of £234 per annum is payable to married male officers Starting salary according to qualifications and experience Generous leave privileges and five-day week Candidates must be in possession of at least an honours degree in metallurgy or metallurgical engineering or equivalent qualification The successful candidate will do research work in the field of ferrous and non-ferrous physical metallurgy The successful candidate will be required to furnish a medical certificate of good health and to become a member of the University Institutions Provident Fund The Council will bear the transportation costs of the appointee and his family from his place of residence to Pretoria Further information and application forms are obtainable from the South African Scientific Liaison Officer Africa House, Kingsway, London W C 2

Applications, giving full details of age marital status qualifications, experience, and the names of referees, must reach the Secretary/Treasurer, C S I R P O Box 395, Pretoria South Africa before March 15 1955 A copy of the application must be sent to the South African Liaison Officer in London

CHELSEA POLYTECHNIC

MANRESA ROAD, S W 3

HEAD OF DEPARTMENT OF GEOLOGY

The Governors invite applications for the post of Head of the Department of Geology, which becomes vacant through the retirement of Dr W F Fleet Candidates should possess high qualifications in geology, and have had experience in both teaching and research Salary scale Grade II (men £1 065 by £25 to £1,215, women £852 by £20 to £972) plus London allowance of £36 or £48, according to age Duties to commence September 1 1955

Further particulars and form of application may be obtained by sending stamped addressed foolscap envelope to the undersigned, to whom applications must be returned not later than February 28, 1955

N M H LIGHTFOOT, M A F R S E
Principal

A RESEARCH FELLOWSHIP OF £750 PER annum renewable annually for a period of three years and tenable at the Chemical Research Laboratory of the Department of Scientific and Industrial Research, Teddington is offered by the Forestal Land Timber & Railways Co Ltd The research will be directed to investigating the function of tannins in preventing corrosion of metals and the results could be made available for a higher degree Applicants should have as a minimum qualification a good honours degree in chemistry and preferably some research experience They should have a particular interest in applying fundamental physical chemistry and physical methods of organic chemistry to problems of industrial importance —Applications, with references should be sent to the Chief Research Chemist, Forestal Central Laboratory, Harpenden Herts

UNITED KINGDOM ATOMIC ENERGY AUTHORITY

WEAPONS GROUP, ALDERMASTON, BERKS

Requires Experimental Officers and Assistant Experimental Officers to assist in the preparation of experimental equipment and in the carrying out of nuclear physics experiments The minimum qualification is higher school certificate (science) or equivalent, but for Experimental Officer posts (minimum age 26 years), possession of a pass degree is desirable Previous experience, although not essential would be advantageous The salary scales are Experimental Officer, £715 to £880 (male) per annum and Assistant Experimental Officer, £288 10s (at age 18) to £640 (male) per annum The successful applicant will be required to join the Authority's Principal Superannuation Scheme to be introduced shortly, and the salary scales quoted above will be enhanced to cover contributions Houses will be available within a reasonable period for married officers who live outside the Establishment's transport facilities

Application form from Senior Recruitment Officer, A W R E, Aldermaston, Berks Quote Ref 349/W G E /34

UNIVERSITY OF LEEDS

Applications are invited for Imperial Chemical Industries Limited Research Fellowships in Bacteriology, Biochemistry, Biomolecular Structure Botany (Plant Biochemistry and Biophysics) Chemical Engineering, Chemistry, Chemistry of Leather Manufacture, Chemotherapy, Colour Chemistry and Dyeing, Engineering (Civil, Electrical or Mechanical), Fuel and Refractories, Geology (including Geochemistry), Metallurgy, Mining (Selective Flotation and Geophysical Surveying) Pharmacology, Physics, Physiology or Textile Industries (Protein Chemistry and Wool Textile Engineering) The Fellowships will be of an annual value within the range £600 to £900 a year according to qualifications and experience and will normally be tenable for three years

Further particulars can be obtained on request Three copies of applications (one in the case of applicants from overseas), together with the names of two referees, should reach the Registrar, The University, Leeds, 2, not later than April 15, 1955

UNIVERSITY OF BRISTOL

DEPARTMENT OF CIVIL ENGINEERING

Applications are invited for a Lectureship (Grade III or II) in the Department of Civil Engineering Applicants should have a good honours degree and some relevant experience, preferably including some research experience in the field of structures or soil mechanics

Applications, including the names of two persons to whom reference may be made should be sent not later than January 31, 1955, to the Registrar The University Bristol 8 from whom further particulars may be obtained

BEDFORDSHIRE EDUCATION COMMITTEE

LUTON COMMITTEE FOR EDUCATION
LUTON AND SOUTH BEDFORDSHIRE
COLLEGE OF FURTHER EDUCATION
Principal W F Stephenson, B Sc, F R I C

Assistant (Grade B) required to organize and teach Geology and Geography to the standard of General B Sc (London) Duties to commence in April The Department is developing rapidly and there are wide opportunities for a person with initiative

Send s a e (foolscap) for application form which should be returned within two weeks of the appearance of this advertisement to J A Corbett Clerk of the Governors, 63-69 Guildford Street, Luton

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF CIVIL AND
MECHANICAL ENGINEERING

Applications are invited for the post of Senior Research Assistant Candidates should have a good honours degree in engineering, practical experience and/or research training Salary scale £550 by £50 to £900

Conditions of appointment and form of applications may be obtained from the undersigned

H PICKBOURNE,
Registrar

UNIVERSITY OF THE WITWATERSRAND

JOHANNESBURG SOUTH AFRIC

Applications are invited for appointm the vacant post of Lecturer in Chemistry qualifications in inorganic and analytical c try will be a recommendation The subs salary scale attached to the vacant post by £50 to £1,150 The initial salary to b to the successful applicant will be dete in accordance with qualifications and expe In addition a temporary cost-of-living all is payable to married men, the present rat £234 per annum An allowance is made t the cost of travelling expenses Duties assumed March 1, 1955 or as soon as p thereafter

Further particulars and information as method of application may be obtained fr Secretary, Association of Universities British Commonwealth, 5 Gordon Square, don W C 1 The closing date for the of applications, in South Africa and Lon January 31, 1955

McMASTER UNIVERSITY

DEPARTMENT OF CHEMISTRY
GRADUATE ASSISTANTSHIPS

Applications are invited for part-time te and Research Assistantships from persons fied to register in courses leading to the and Ph D degrees in chemistry Assista normally carry a yearly stipend of $1, $1 600 Assistants are required to devot to ten hours per week to duties duri academic session (October to April inclusiv may devote full time to their research dur summer Research is in progress in th lowing fields mass spectrometry nuclear c try radiochemistry natural isotopic abu ratios and their biological and geological ficance isotope effects, organic reaction m isms physical chemistry of high-polymer tions isolation and structure of plant alk biogenesis of the thyroid hormone interm metabolism inorganic analytical methods

Interested persons should write to Dr Graham Chairman of the Department of C try Hamilton College McMaster Univ Hamilton Ontario Canada

UNIVERSITY OF MANCHEST

Applications are invited for posts of Le in Engineering Civil engineering cand should have particular interest in elas hydraulics or surveying, mechanical engin candidates should have particular interest i transfer, fluid mechanics thermodynamics a applied mechanics The present salary scal to £1 100 per annum but is under review salary according to qualifications and exper Membership of F S S U and children's allo scheme Applications will be considered engineers who would be interested in a tem appointment of two or more years

Applications should be sent not later February 15 1955 to the Registrar, The versity, Manchester 13, from whom further culars and forms of application may be obt

ST THOMAS'S HOSPITAL MEDICAL SCHOOL

A Lecturer in Applied Pharmacology and peutics is required by the Department of peutics Salary will be according to the sca a Junior Lecturer or Lecturer according t perience, with family allowance

Applications, giving full particulars an names of two referees should be sent February 8 to the Dean, St Thomas's Ho Medical School, London, S E 1

UNIVERSITY OF CAMBRIDG

VACANCY EXISTS AT ALUMINIUM ratories Limited, Banbury Oxon, for a nical engineering graduate interested in deformation research Preference will be to a graduate who has already had some ch experience in this field, and who has a ledge of current theoretical and experimental iques in plastic flow problems Initially, the sful applicant would be required to continue isting programme of research into the role ibricants in metal deformation processes would be opportunity for a suitable candi- to lead a section engaged in general metal mation researches within one or two years ssion of a higher degree would be an advan- in this latter connection —Applications full particulars of past training and experi- should be addressed in confidence to the tor of Research Aluminium Laboratories ed Banbury Oxon

RRANTI LIMITED EDINBURGH, RE- n graduate Physical Chemist to build up and charge of a small laboratory group and to in co-operation with development teams en- on the design of novel precision electrical mechanical equipment required by high ty government contracts The problems g from this work cover a wide field and de metallurgy properties of materials appli- ns of resins, lubricants anti-corrosion surfac- es etc , and there is full scope for initiative i expanding organization This is a senior ntment and candidates should preferably had several years industrial experience The will be commensurate with the responsi- s —Applications should be made to the nnel Department, Messrs Ferranti Ltd , e Toll Edinburgh 5, quoting reference .C

E BRITISH CERAMIC RESEARCH ciation has vacancies for honours graduates ysics or chemistry for work on a wide range roblems in the ceramic industry Previous rience in this field is not essential The ap- ments, which carry superannuation under U , are permanent and offer good prospects y will depend on age qualifications and ex- nce, but will be within the range £450 to for Scientific Officers, and £830 to £1,070 for r Scientific Officers —Applications together full details should be sent to the Director of rch Queens Road, Penkhull, Stoke-on- t

ADUATE CHEMIST OR ENGINEER RE- d by Research Association to apply in mem- factories results of research Position suit- young man recently qualified or some ex- nce Good starting salary excellent pros- , Pension scheme —Write particulars train- experience to Director British Launderers' rch Association The Laboratories, Hill View ens, Hendon N W 4

QUALIFIED CHEMIST IS DESIRED BY ll-known Yorkshire firm manufacturing surgi- plasters and dressings and pharmaceutical ucts The successful applicant will be re- d to take up the position of Principal Assis- to the Control Chemist in their Hull factory num second-class honours in chemistry or I C by examination necessary An interest nalytical techniques and physical testing is tial although the post is partly supervisory ous experience is desirable, though not essen- and the position is for a man below 30 years ge —Reply to Smith and Nephew Research Hunsdon Laboratories, Ware, Hertfordshire

IPRINOL LTD WISHES TO APPOINT A nical Sales Representative to forward the ntation of new fungicides Applicants d preferably possess a qualification in myco bacteriology or an allied science, and pre- experience in technical sales Technical sentatives with sales experience in manu- ring or processing industries, where con- tion has to be given to the possibility of l or bacteriological attack, may be con- d —Full details of qualifications and experi should be sent in the first place to Personnel ger Imperial Smelting Corporation, Ltd ndrew's Road Avonmouth, quoting Refe- CUL/N

IGINEER AGED 25 /35 WITH ELECTRI- r physicist degree required by Cable Com- in London area for development work on g equipment for telecommunication cables anent and pensionable position at salary nensurate with experience and qualifications ply, giving full particulars to Box 617, T G and Son, Ltd , 143-147 Regent Street lon, W 1

A PROFESSIONALLY QUALIFIED Engineer or Physicist is required for the development of electrical spark erosion methods as applied to the cutting of hard metals —Applicants should write to the Director of Research, British Thomson-Houston Co Ltd , Rugby, quoting reference BL, and stating their age, qualifications and experience

METALLURGICAL CHEMIST REQUIRED, for a large organization now situated in London but soon moving to Debden, near Loughton Essex Applicants should have experience in electro-deposition processes, modern testing and quality control techniques, and preferably some experience in a field of research The post would carry responsibilities for production by existing processes for technical developments, and for the replanning at the new factory which these developments would necessitate The appointment would be permanent and pensionable under a non-contributory scheme and facilities for house purchase would be made available if required —Candidates, who should be British by birth and under age 35, should write, stating age full details of education training and experience, to Box R 796 c/o Streets 110 Old Broad Street E C 2

REQUIRED, A QUALIFIED CHEMIST TO take charge of small Pharmaceutical Analytical Laboratory, preferably with experience in this work The laboratory is situated in Bristol Salary £600 to £700 according to experience and qualifications —Applications, giving full details to be sent to Box 616, T G Scott and Son, Ltd 143-147 Regent Street, London, W 1

REQUIRED, A QUALIFIED CHEMIST, TO take charge of small Pharmaceutical Analytical Laboratory preferably with experience in this work The laboratory is situated in Bristol Salary £600 to £700, according to experience and qualifications —Applications, giving full details, to be sent to Box 620, T G Scott and Son Ltd 143-147 Regent Street London W 1

BAKELITE LIMITED HAVE VACANCIES at their Aycliffe (Co Durham) works for two young qualified Chemists and a young Chemical Engineer Applicants should have a B Sc degree or equivalent, and some industrial experience The work concerns chemical and chemical engineering investigation into problems arising in the manufacture of P V C resins and compounds and the manufacture of products based upon P V C resins Salaries will be in the range of £650 to £850 per annum in accordance with age and experience —Applications should be addressed to the Personnel Manager Bakelite, Limited, 12 Hobart Place London S W 1

RESEARCH AND DEVELOPMENT Ferodo, Limited have vacancies for both Technical Assistants and graduate Technical Officers The Assistants should preferably have advanced level G C E in physics or chemistry, while some industrial experience, particularly of moulding or related technologies, would be advantageous The work is concerned with the development of various types of friction products and offers good opportunities for men with initiative and enthusiasm for the development of products in a new field Contributory pension scheme compulsory —Applications giving full details of age, education industrial experience, etc , and quoting T/RAD, to Personnel Manager Ferodo Limited Chapel en-le-Frith via Stockport

TECHNICAL SALES REPRESENTATIVE age 25 to 32 of good approach required by well known Company, to specialize in non-selective weed control products Knowledge of soils, weeds and mechanical appliances desirable Five-day working week —Apply in writing, stating qualifications and salary required, to Box 8253 c/o Charles Barker & Sons Ltd , 31 Budge Row London E C 4

APPLICATIONS ARE INVITED FROM RE-cently qualified male Chemists for interesting progressive post in cereal laboratory Work will involve non-routine analysis and research Applicants should be in 20 to 25 age group Five-day week and pension scheme in operation —Write, giving full particulars of academic qualifications and experience to Personnel Manager (L), Quaker Oats, Limited Bridge Road, Southall, Middlesex

WEST OF ENGLAND MANAGER RE-quired by dealers in chemical and scientific apparatus —Send full details of experience age and salary required to Box 615, T G Scott and Son, Ltd , 143-147 Regent Street, London W 1

TEXTILE CAREERS BRITISH NYLON Spinners, Limited have several vacancies for young graduates who will be given extensive technological training, enabling them to become specialists in this expanding organization The ideal qualification is a university degree in physics engineering or textiles, and candidates must have a natural bias towards applied work The selected candidates will be put to work under the supervision of experts, and training will include a thorough grounding in the manufacturing of yarns and fibres, and later in their development and processing to meet changing market requirements Upon successful completion of this training, it is intended to employ these graduates in responsible positions on either technical development and experimental work or in the field of technical service There will also be openings on the commercial side of the business, in which specialized knowledge can be applied to the development of new end-uses for the Company's products A realistic salary will be paid during training and these vacancies offer exceptional opportunities to men who are willing to work hard with a specific object and in a climate of technical stimulation and progress —Letters should contain full details of academic achievements and a frank statement of ambitions and inclinations, these should be addressed to the Personnel Manager, British Nylon Spinners Limited Pontypool and will be treated with strict confidence Candidates invited for interview will be given a very clear impression of all that is implied by this new type of career

THE ENGLISH ELECTRIC COMPANY IN-vites applications for progressive posts in the Mathematical Physics Group of the Guided Weapons Division Luton The work comprises theoretical analysis relating to a wide range of engineering problems and the application of electronic analogue and digital computers to their solution Applicants should hold at least an honours degree in mathematics, physics or engineering and should preferably have had several years' experience in engineering research The salary will be in accordance with qualifications and experience Assistance with housing accommodation may be given —Applications to Dept C P S 336-7 Strand, W C 2 quoting Ref S A 50B

SMITHS AIRCRAFT INSTRUMENTS LTD have vacancies in their Engine Controls Department for Senior and Junior Graduate Engineers and Physicists interested in research and development of automatic controls for aero gas turbines Experience in, and knowledge of theoretical and/or practical aspects of servo mechanisms, or magnetic amplifier and electronic techniques or electro-mechanical equipment, together with an appreciation of the requirements for airborne equipment, would be an advantage Salary would be commensurate with qualifications and experience —Apply giving details and qualifications, quoting Reference 49/EN to The Personnel Department, Smiths Aircraft Instruments Ltd , Bishop's Cleeve, near Cheltenham, Glos

BACTERIOLOGIST WITH UNIVERSITY degree, wanted to take charge of laboratory producing veterinary sera and vaccines Must be experienced in laboratory techniques and have had at least two years' practical experience Knowledge of veterinary work an advantage, but not essential —Box 619 T G Scott and Son, Ltd 143-147 Regent Street London W 1

A LARGE AND WELL-KNOWN CHEMI-cal Company invites applications for an important post as Works Manager of a modern chemical plant Applicants should be aged 38 to 45 and have a degree in chemistry or chemical engineering Considerable experience of management is essential and candidates should have the ability to apply modern management methods and to lead a production team A substantial salary will be paid Further details of the post, its location and the company's facilities will be given to those selected for interview —Applications which will be treated confidentially, should give full details of qualifications experience and present salary and should be addressed to Box 8252 c/o Charles Barker and Sons Ltd , 31 Budge Row London E C 4

ENGINEER AGED 22/35 REQUIRED BY Cable Company in London area for testing and maintenance of electronic equipment in new instruments for automatic testing of telecommunication cables —Apply giving full particulars to Box 618, T G Scott and Son, Ltd , 143-147 Regent Street London W 1

LADY CHEMIST GRADUATE OR H N C required for analysis of electroplating and allied solutions —Apply Electro-Chemical Engineering Co , Ltd , 161 Queens Road Weybridge Surrey

Advertisers please note You must add "Apply Employment Exchange" unless the employment advertised or the workers required are excepted under the Notification of Vacancies Order

THE SHELL PETROLEUM COMPANY, Limited, invites applications from Organic Chemists with a good honours degree, or equivalent, and preferably under 30 years of age, for post at their research centre, Thornton-le-Moors Cheshire The position entails maintaining close contact with the activities of the laboratories, and the progressing of patentable aspects of investigations in the petroleum lubricants and derived chemical fields Starting salary according to qualifications and experience, pension benefits —Write, giving full details of age qualifications, marital status, to the Shell Petroleum Company, Limited, Staff Department (R/T), St Helen's Court, London, E C 3

NUCLEAR PHYSICS SECTION OF A laboratory for long-term research The following appointments are available Research Physicist A good honours degree or Ph D in physics is required Applicants should preferably have a nuclear physics background or have some experience of research in this branch (and have fulfilled their obligations under the National Services Act) Research Assistant Applicants must have reached higher national or pass degree standard in electrical engineering or physics, and have had experience in electronics or with electrical or vacuum apparatus —Applicants should send full particulars in writing to the Personnel Officer, Research Laboratory, Associated Electrical Industries Limited, Aldermaston Court, Aldermaston, Berks

RESEARCH METALLURGIST REQUIRED to undertake investigations on metallurgical problems associated with the machining and cold forming of metals Candidates should possess a good degree The position is permanent and there are good prospects for advancement Superannuation scheme in operation —Send full details, including age experience, qualifications and salary required to Box 614, T G Scott and Son, Ltd , 143-147 Regent Street London W 1

WANTED A MAN TO TAKE CHARGE OF a new division on nuclear pile instrumentation The division is small at the moment but expected to expand considerably in the coming years and a very attractive career is offered to the right man Experiehce in servo systems and electronic circuitry is essential —Particulars, quoting reference R13, to the Personnel Officer, Ericsson Telephones Limited, Beeston, near Nottingham

ORGANIC RESEARCH CHEMIST REquired by company manufacturing fine and technical chemicals The work will be mainly on hydrogenation of aromatic compounds, with particular reference to stereochemistry of products Honours graduates preferred, some industrial research experience desirable Initial salary up to £850 The post can be regarded as permanent and pensionable —Apply, in writing, stating age and giving details of education and experience to Personnel Manager, Howards of Ilford, Ltd , Ilford, Essex

APPOINTMENTS WANTED

GRANTS & SCHOLARSHIPS

NUFFIELD FOUNDATION

FELLOWSHIPS AND SCHOLARSHIPS IN DENTISTRY

The Nuffield Foundation invites applications from citizens of the United Kingdom, for Fellowships and Scholarships in Dentistry To help the advancement of teaching and research on dental health and disease, the Foundation is prepared to award a number of fellowships (i) to enable selected men and women with dental qualifications to receive such additional training in pure and applied science as is desirable to fit them for an academic career in dentistry (but not to obtain a medical qualification), and (ii) to enable selected university graduates in medicine and science to receive training that will qualify them to undertake teaching and fundamental research on dental health and disease The Foundation is also prepared to award a limited number of scholarships to assist students of outstanding ability attending a university dental school to devote one or two years to further studies of the basic sciences

Applications for fellowships should be received by March 1 annually and for scholarships by June 30 annually Copies of the conditions of both fellowships and scholarships and the application forms are obtainable from the Director, The Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N W 1

L FARRER-BROWN
Director of the Nuffield Foundation

NUFFIELD FOUNDATION

BIOLOGICAL SCHOLARSHIPS AND BURSARIES

The Nuffield Foundation, as part of its programe for the advancement of biological studies, is prepared to offer for the academic year 1955-6 a limited number of scholarships and bursaries to enable persons who have graduated in physics chemistry, mathematics or engineering, but who have had no training in a biological subject, to receive such training in biology as will enable them in due course to undertake research and teaching in the United Kingdom in the biological sciences The scholarships, which are senior awards, are intended for persons who have already undertaken some postgraduate research in their own subject The bursaries are intended to enable those who have recently graduated to complete a course of training in biological subjects, including, if considered necessary, a full honours degree course in biology In the case of both scholars and bursars the Foundation will pay the cost of university and/or college fees in addition to a maintenance award Graduates of universities in the United Kingdom, of either sex and preferably between the ages of 22 and 35, are eligible to apply

Applications for awards in 1955 must be received before April 1, 1955, by the Director, The Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N W 1, from whom further particulars and application forms can be obtained

L FARRER-BROWN,
Director of the Nuffield Foundation

FISHERIES RESEARCH STUDENTSHIP

The Secretary of State for the Colonies will award a Fisheries Research Studentship with a view to fitting the holder for fisheries research work in the Federation of Malaya as a member of the Research Branch of Her Majesty's Oversea Civil Service The work will involve study of the digestive enzymes of cultivated fish, with a view to securing the best use of natural and added foods in tropical fishponds, and chemical and biochemical analyses of the pond water, mud, plankton and fish, aiming at an increase in the efficiency of fish farming The Studentship will be tenable at a United Kingdom University, for twelve months in the first instance The holder will be required to undertake to serve subsequently for at least three years overseas Minimum academic qualification a good second-class honours degree in biochemistry, physiology, zoology or botany The value of the Studentship is between £25 and £34 10s a month, tax free according to the location of training with additional allowances for married candidates Tuition fees and certain other expenses will be paid in addition Applications are invited both from persons already possessing the required degree and from those who expect to qualify in 1955

Applications to the Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S W 1, quoting reference BCD 418/324/01

For your vital Laboratory work . . .

Special hard porcelain for chemical and scientific use has been produced by Royal Doulton for over 30 years It combines the following advantages

- Excellent resistance to high temperatures and to thermal shock caused by temperature fluctuations
- The glaze, which is perfectly married to the body of the ware, withstands the strain of heating up and cooling down
- The use of first quality raw materials gives the finished product high resistance to chemical attack
- The raw materials are carefully selected to ensure freedom from iron contamination.
- High mechanical strength is apparent even in the thin-walled articles normally used in laboratory practice

Write for further details to Doulton & Co. Limited, Industrial Ceramics Division, Dept. C, Doulton House, Albert Embankment, London, S.E 1.

SECTION PERFECTION

The **Reichert OME Sliding Microtome,** shown above, is undoubtedly the best all-round instrument available It will cut equally well paraffin, celloidin, and frozen specimens, and experience has shown again and again that this instrument is capable of solving the toughest and most difficult sectioning problems The **OME** microtome incorporates fully automatic feed from 1 to 30 microns, universally adjustable knife clamp to take knives between 160 and 240 mm length and the invaluable Naples object clamp for precise block location

The **Freezing Microtome OMP** is remarkable for the design of its knife carrier which permits correct cutting angle adjustment and is permanently supported by the knife track Equally well known is the **Rotary Microtome OMS** with Automatic Ribbon Conveyor

We keep comprehensive stocks of superior quality microtome knives, hand-made for us in Heidelberg by people who have specialized in this field for many decades

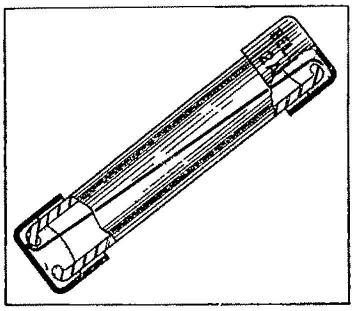
COMPONENTS FOR THE LABORATORY



FUSE-LINKS OF REAL PRECISION (B.S. 646 (B))

The L1055 is available in ratings from 60 mA to 25 A, but at present this **new construction* applies only to ratings of 500 mA and over It is hoped to include the lower ratings later, but in the meantime, industry will be supplied with our original design in which we have always minimized the problems that "all-in-one" construction obviates

**** Caps that come loose are things of the past They are now locked to the glass by a unique internal soldering technique, which bonds caps, filament and glass into one unit. The glass has to break before the caps will move, and as caps are coded, the risk of replacement by wrong ratings is obviated Mechanically and electrically this is a better fuse-link.***

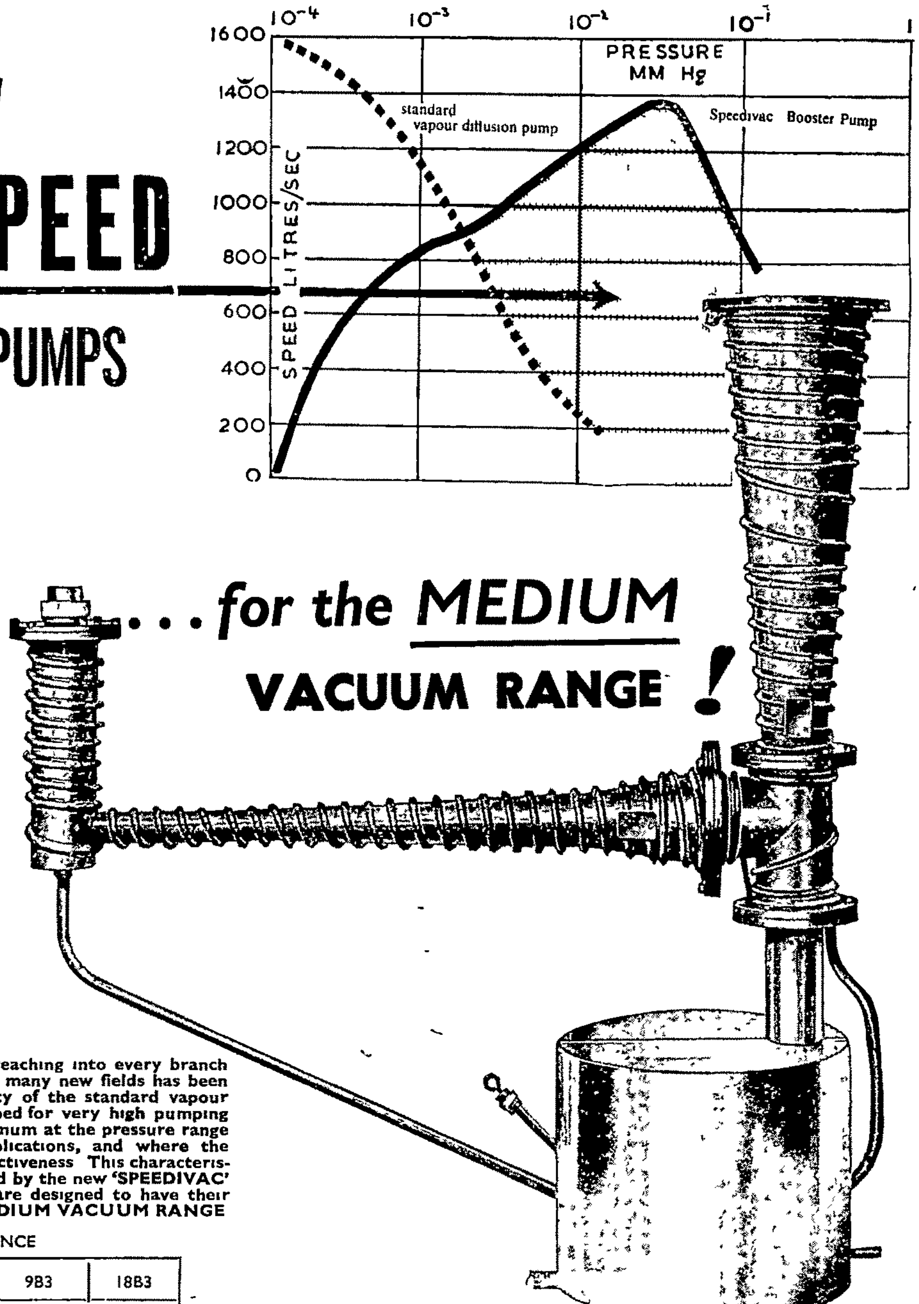
NEW
HIGH SPEED
VAPOUR PUMPS



. . . for the MEDIUM VACUUM RANGE!

High vacuum technique is reaching into every branch of industry, but progress in many new fields has been impeded by the unsuitability of the standard vapour pump, which, though developed for very high pumping speeds, is far from its maximum at the pressure range important to the new applications, and where the rotary pump is losing its effectiveness. This characteristic speed 'GAP' is now closed by the new **'SPEEDIVAC' BOOSTER PUMPS** which are designed to have their maximum speeds in the **MEDIUM VACUUM RANGE**

PERFORMANCE

	9B1	9B3	18B3
ULT VAC mm Hg	BETTER THAN 10^{-4}		
Peak speed lit./sec unbaffled	40 at 1·85 kW	850 at 2·25 kW	1300 at 6·4 kW
Recommended backing pump displacement, lit./min	450	450	2800
Recommended backing pump	1SC450	1SC450	1SC3000

Other Valuable Features

- ★ *De-gassing Vacuum Furnaces Metallurgical and chemical processes Vacuum stills Impregnation*
- ★ *Backing pressure performance enables gas flow to be handled by smaller backing pump and lines*
- ★ *Economical operation compared with alternative evacuation methods*
- ★ *The new booster pumps backed by a 'Speedivac' gas-ballast rotary pump maintains a very high exhaust rate at critical pressures for contaminating process vapours*

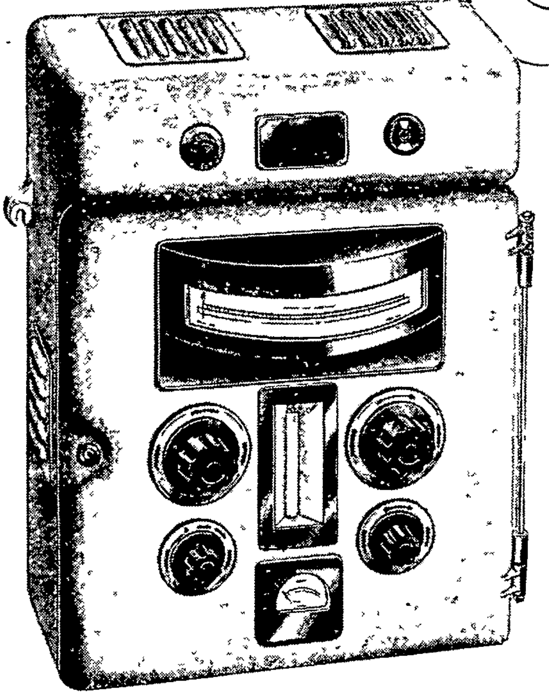
BAKER PLATINUM

deoxo Indicator



FOR THE DETECTION AND CONTINUOUS MEASUREMENT OF TRACES OF OXYGEN AND HYDROGEN IN GASES

During recent years many industries have sought a practical and accurate means for detecting and measuring small quantities of oxygen present as an impurity in other gases. The Deoxo Indicator has been designed to supply this need. Ruggedly constructed and capable of operation for long periods with little or no attention, the instrument is suited both to industrial and to laboratory use. It indicates the presence of from .001% to 1% oxygen in inert gases, hydrogen, nitrogen, carbon dioxide and saturated hydrocarbon gases. The accuracy of indication is conservatively estimated at ±2% of the value of full scale reading

The Deoxo Indicator may be used to detect and measure hydrogen (instead of oxygen) impurity in inert gases, nitrogen, carbon dioxide and saturated hydrocarbon gases.

★ *A copy of the illustrated leaflet giving full details of the Deoxo Indicator will be forwarded on request. Technical representatives are always available for consultation and advice*

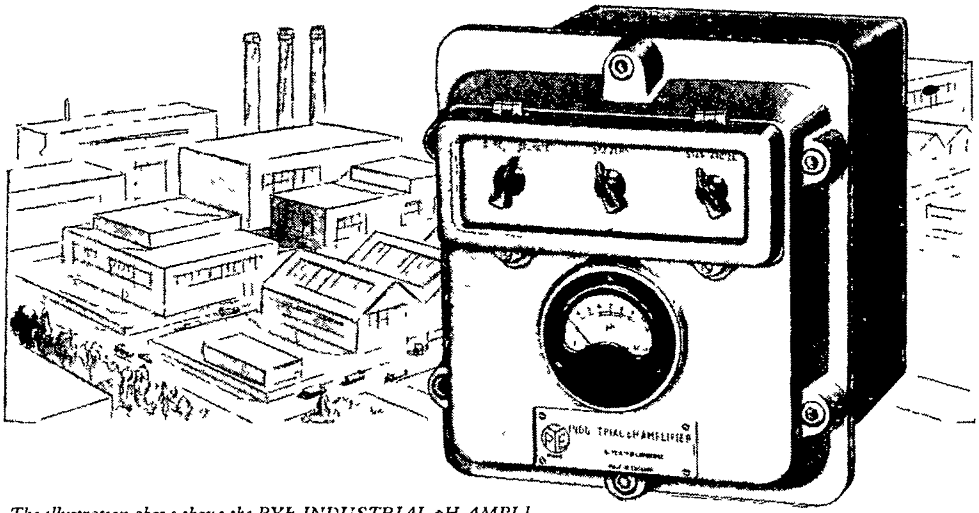
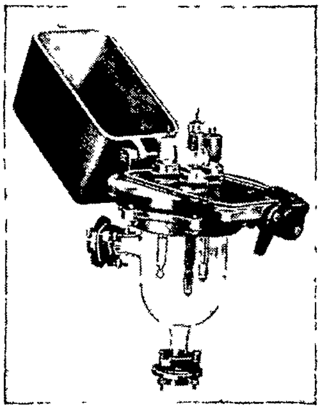
PYE INDUSTRIAL pH AMPLIFIER



The illustration above shows the PYE INDUSTRIAL pH AMPLIFIER Cat No 11400, which is built into a flame-proof case, constructed for easy servicing and designed for the continuous measurement of pH values It will drive controllers, recorders, remote indicators and alarm-relays Below on the left is illustrated the Continuous Flow Electrode Assembly, Cat No 11420 and on the right the Immersion Type Electrode Assembly, Cat No 11405 May we send you details of these instruments?



IN every industry where water or chemical solutions are used, money can be saved and efficiency can be increased through effective pH measurement and control The exact measurement of acidity and alkalinity will readily provide the key for methods of eliminating waste, reducing maintenance and corrosion, developing new products and improving product quality at the lowest possible cost

The glass electrode pH Amplifier operated from the mains, and presenting a direct indication, provides the simplest, quickest and most efficient method of measuring and controlling pH The use of this type of instrument is quickly becoming a major feature of the current trend towards instrumentation in industry

"Spectrosol"

Hopkin and Williams Ltd. are now in a position to supply the following solvents in the " Spectrosol " range. These solvents are specially purified for absorption spectroscopy and are supplied only by Hopkin and Williams Ltd.

CODE NO.	
2858.5	**Carbon Tetrachloride**
3073	**Chloroform**
3566.3	**Cyclohexane**
4118.5	**Ethyl Alcohol**

A signed analytical certificate indicating the spectroscopic purity of the contents is supplied with each container

The rapidly increasing use of quartz spectrophotometers in all types of industrial and research laboratories has created a correspondingly increased demand for solvents of adequate ultra-violet transparency, and it is in this branch of the spectroscopic field that "Spectrosol" solvents will find their main application. Further additions to this range of solvents will be announced from time to time as they become available. A leaflet describing the present range of " Spectrosol " solvents is available on request.

" Spectrosol " Solvents
are available only from
Hopkin & Williams Ltd.

SCIENCE IN INDUSTRY: MATERIAL AND HUMAN FACTORS

THE working conference on research and industrial productivity which was arranged by the Department of Scientific and Industrial Research in association with the British Productivity Council (see *Nature*, January 8, p. 66, 1955) was concerned essentially, as Lord Salisbury emphasized at the opening luncheon, with the scientific aspects of productivity. Its discussions in general did not deal directly with research in technology; they were concerned rather with the directions in which further research in such matters as alternative methods of working, work study and industrial operations and relations generally could contribute to the more effective utilization of existing knowledge, the reduction in the time required for the development of technical innovation and the improvement of industrial productivity in general. The conditions which determine the rate of technical innovation were critically and carefully examined, and numerous suggestions were made as to further scientific studies which might enable obstacles to be removed and so improve the standards of both management and operatives as to increase productivity.

The efficiency and progress of industry, as Lord Salisbury observed, is not solely a matter for industry itself. It is a matter with which any government must be concerned, and it may not be without value that the Conference should have drawn from Lord Salisbury this frank admission of government responsibility and of the contribution which the Government itself could make to industrial productivity, not simply by encouraging progressive industry but also by shaping national economic and financial policies so as to create a more favourable climate for higher productivity. Nor is this a matter of party politics. Neither major political party has yet given evidence that it is prepared to make the impartial approach that is required, or to undertake the essential educational work, above all when that runs counter to some particular political prejudice or party dogma.

Here indeed are to be found the two main threads that seem to run through the discussions and which are inextricably mixed. First are the recognition and demand for more quantitative study of industrial operations of all kinds and at all levels, from that of research to development, production, market research and distribution, and using all possible appropriate methods—operational research, measurement of productivity, work study and the rest. When such quantitative study has provided the factual basis for decisions, those decisions cannot be taken and put into practice without consideration of the human and psychological elements. The importance of these elements in making decisions, in providing a sense of participation and in removing the frustrations of industry was the second main thread in the discussions.

That aspect was emphasized from the start. Lord Salisbury said he does not believe it is possible to over-estimate the importance of the psychological approach; this might play an indispensable part in the future in counteracting that boredom and fatigue which are the inevitable result of the increasing mechanization of industry. Moreover, as Sir Ben Lockspeiser pointed out, while the fully automatic factory, for example, is on its way and we cannot choose whether or not to make changes which carry economic advantages in competitive markets, such changes demanded by technology are apt to conflict with habits of work and ideas of management. Some of the old conceptions still current on both sides of industry are quite out of keeping with modern technology, and much fresh thought is demanded—of governments as well as of employers' federations and trade unions—on human as well as technical problems, if an old traditionally minded democracy such as ours is to preserve its freedoms and earn its living in a competitive world.

Sir Ben described the changes connoted, for example, in the coming of the automatic factory as tantamount to a second industrial revolution; but what seems equally clear from the discussions at this Conference is the extent to which a revolution in thought is still required on both sides of industry and indeed among politicians. Even in the research programmes of the Department of Scientific and Industrial Research, Sir Ben noted, it is necessary to study more closely the needs of industry and the conditions under which it operates, to think in terms of costs and economics and human values, as well as of science, in order to achieve right emphasis and apply the results successfully. In confirmation of this, in speaking on economic factors in planning research, Dr. R. M. Lodge, research manager of British Nylon Spinners, stressed the necessity for much more careful attention in planning on the production and sales side a milieu receptive to research ideas, and also insisted on the importance of the human element; he referred particularly to the importance of planning consciously to provide the right atmosphere in which research can flourish and the dependence of research to-day on group- or team-effort.

Dr. Lodge also suggested that, with the present scarcity of scientific and technical man-power, it might be necessary to give much more thought and attention to the best possible means of using the available qualified men, even if it caused rearrangement of the traditional laboratory organization so as to relieve the limited number of more highly trained men, and those most capable of original thinking, of routine activities. The most effective use of our resources of scientific man-power to-day will scarcely be secured without pursuing this principle much more carefully and thoroughly, not only in industry but also elsewhere, including the university laboratories and research institutions, and the science teachers in the schools and technical colleges. The attempt to do so, moreover, will frequently encounter similar obstacles to those which hinder attempts to secure the adoption of technical innovations or more efficient methods of working, namely, lack of human understanding and co-operation.

The critical factor is indeed everywhere the psychological one, and ultimately at whatever level the task of improving industrial productivity is approached, from the research department to the sales department, the real problem is one of communication, in the true sense of the word—of promoting a clear understanding on the part of all concerned of what requires to be done and why, of how it affects them and the contribution which they are called upon to make. While the discussions at the Conference stressed the need for more quantitative knowledge and the importance of taking full account of the human factor, they equally made manifest the extent to which the whole of the research programme of the Department of Scientific and Industrial Research and of the research associations has already been influenced by such ideas and is aimed in one way or another at increasing industrial productivity, interpreted in the broadest sense. Still more, however, did the Conference manifest the extent to which human neglect, prejudice or ignorance persist in preventing the nation from reaping the full benefit of existing knowledge and drawing the greatest possible advantage from its natural resources, even those that, like fuel, are dwindling seriously.

One of the most disturbing papers in this respect was that of Mr. K. T. Spencer, chief scientific adviser to the Ministry of Fuel and Power, on the availability of fuel and its efficient use. Mr. Spencer, recalling the past dependence of the industrial progress of Britain on cheap coal, said that it has yet to be proved whether nuclear energy can restore the age of abundant energy, and at best many years must pass before nuclear energy can replace coal as our main source of energy. Meanwhile, we have to face a continuing fuel shortage which within the next decade may well involve a gap between supply and demand of some 20 million tons of coal per annum. So far, the increasing requirements of industry, with the production of coal declining, have been met by increasing efficiency of utilization, by reducing exports and by increasing the use of oil. Mr. Spencer reminded the Conference that hitherto mechanization has given no spectacular increase in output of coal, and the quality has deteriorated and is likely to continue to do so. It would be unrealistic, therefore, to rely on coal production increasing sufficiently to meet our requirements, and it would be equally unwise to regard with complacency an increasing dependence on imported petroleum. The soundest policy for filling the gap, he said, is to increase the efficiency with which fuel is used.

It is here, in his revelation of the extreme variations in the efficiency with which coal is at present used by different industries and in one and the same industry, that Mr. Spencer is startling and even alarming. He quoted evidence of waste that has persisted virtually unchecked for eighty years since it was condemned by a Commission of Inquiry appointed in 1871; during that period, according to a survey made by the Ministry of Fuel and Power in 1953, the average efficiency of the shell-type boiler had increased by about 10 per cent. Indeed, figures quoted by Mr. Spencer show that in some industries, such as paper and board, bricks and fireclay and cotton, productivity per ton of coal decreased between 1935 and 1948, although on the whole productivity per ton of coal slightly increased. But in individual industries the yield per ton of coal can vary hundredfold: for grain-drying, for example, from 5·6 tons to 224 tons; for beer from 18·5 to 112 barrels; for biscuits from 1 to 20 tons; in laundry work from 0·4 to 5 tons; in bronze and brass founding from 1·7 tons to 20 tons for billets and ingots, and from 0·2 to 2·5 tons for castings; and in continuous kilns for building bricks from 4·8 to 44·7 tons. An investigation of some twenty breweries, for example, by the British Coal Utilization Research Association indicated simple methods the adoption of which would save about 200,000 tons of coal per annum; and, quite apart from this, Mr. Spencer was able to point to some equally startling savings which could be achieved by the substitution of the most efficient plant for the inefficient plant so often used.

The challenge to thought represented by Mr. Spencer's paper is unmistakable, but the very magnitude of the task before us underlines the importance of the task of education. Clearly, a large amount of the information required for a fuel economy advisory campaign already exists; and clearly also the importance of there being within each firm someone abreast of scientific advance and able to appreciate its bearing on the technical activities of the firm is again demonstrated. The major problems are those of the communication of existing knowledge in the most appropriate and effective way, and the means by which the psychological and human obstacles to its utilization are to be overcome.

Here is a challenge to fresh and constructive thought, and indeed to further investigation, as was elaborated in some detail in various papers at the Conference, notably in those by Mr. N. Fleming and Mr. R. M. Currie. Though due weight was given to the technical factors, there was no disposition to over-rate either such factors or the economic factors on which other speakers like Mr. A. H. Wilson, Dr. C. B. Frisby or Mr. D. A. Oliver, for example, laid stress in considering obsolescence, the design of equipment, the organization of work and the exploitation of mineral resources. Whatever fresh facts are required as basis for decisions in particular fields, the overall need is for clear unprejudiced thinking about the whole situation, taking into account the scientific and technical as well as the economic and psychological factors before determining policy and action.

This challenge to study and thought emerges again and again in the most diverse papers presented at the Conference. It is the keynote, for example, of Prof. C. F. Carter's analysis of the economic factors in technical innovation and the justification for the studies of the obstacles to such innovations in business which are at present being examined by the Science and Industry Committee of which he is chairman. Prof. S. Zuckerman's discussion of the utilization of raw materials, with its emphasis not only on efficiency and the elimination of waste both in production and use, but also on the desirability of living on income in this respect rather than on capital, is no less challenging. Long-term appreciations of the supply position make bigger demands on forethought than the short-term views which he criticized, and thought as well as fresh investigation will be required if renewable resources like cellulose are to replace wasting assets such as coal and petroleum as raw material for synthetic processes. Prof. Zuckerman pointed out how far we are from significant supplies of synthetic foodstuffs: the mechanism of photosynthesis is not yet fully understood, let alone reproduced in the workshop. It would be of very doubtful value to base any efforts in that direction other than on the production of nutrients obtainable at low cost of energy and materials from renewable assets.

The possibility of conflict between short-term and long-term considerations was admitted by Prof. Zuckerman, and it should be obvious that, when all that is possible has been done to secure the economic elimination of waste in production and utilization and the efficient use and co-operation of labour, the selection of materials and processes contributing to the soundest economy and conservation of natural resources involves decisions which can scarcely be taken without government approval and support. If little was said specifically on this point at the Conference, apart from Lord Salisbury's rather oblique reference at the opening luncheon, the vital bearing of government policy on industrial productivity and the conservation of resources was repeatedly indicated. The large savings in coal per passenger or vehicle mile which Mr. Spencer gave as possible by substituting electric trains for steam trains, or diesel locomotives or diesel road coaches for steam locomotives and trains, are unlikely to be realized without a change in government policy towards the re-equipment of British railways, for example. If, moreover, British industry is, as has been suggested, less willing than formerly to take risks, government policy can be the determining factor as between supporting weakness and encouraging initiative and enterprise.

Even here, however, we are concerned with the human factor. In the re-equipment of the railways, for example, the provision of the capital resources may well prove a small problem compared with that of the human adjustments and the revolution in working practices that will be involved in the replacement of steam working and the efficient use of new equipment. The problem of education and communication of ideas, knowledge and purpose is fundamental at all levels. Here the Conference seemed to be somewhat disappointing. What is needed even more urgently than the investigations in the field of work study, which Mr. Currie suggested, is a more determined effort to promote the understanding and confidence between management and workers on which high productivity depends.

Admittedly, evidence that management is alert and competent to take full advantage of advances in technique can help to establish such confidence. So, too, could the knowledge that research, such as Mr. Currie suggested, is proceeding into improved methods of operating, from the health and safety points of view, the economic, the physiological and the psychological points of view. But if the results of those researches are to be fruitful, the attempt to encourage receptivity to new ideas and practices must be proceeding now, and restrictive practices and ideas attacked at all levels, alike among employers' associations and among the trade unions. The promotion of a climate of opinion favourable to technical innovation and industrial productivity should receive the first priority.

The Conference gave little lead as to how this task is to be undertaken, or as to the most appropriate methods by which it could be approached. Dr. C. B. Frisby indicated the need for further consideration of means of communication as well as for the co-operation of different specialists. Dr. A. King, in summing up, recognized the value of a combined approach, and he and Dr. F. C. Toy both emphasized the extent to which the Department of Scientific and Industrial Research, with its network of research associations, is now regarded by the Government as one of the major means for transmitting ideas to industry. The other main national agency is the British Productivity Council, with its regional organization and circuit system, which endeavours to bring management and workers together in every main industrial area, using modern methods of presentation. These bodies have already done much, and it is probable that more will be done, particularly by the research associations, as their knowledge of the human aspects of production and innovation increases. If, however, the full co-operation of the human element is to be secured in the application of science in industry, commerce and the public services, from the level of director to that of operative, this problem of communication and the most effective methods by which it is to be achieved are, as Mr. L. T. Wright insisted at the Conference, of supreme importance. It is the problem to which, above all, the Lord President of the Council should give his immediate attention in following up the Conference, and it could fittingly engage the attention of the Parliamentary and Scientific Committee as well as of the British Productivity Council and all those bodies which, whether represented or not at the Conference, are concerned with the development of industry and the economic future of Britain.

FORMATION AND COMPOSITION OF COAL

Coal

Its Formation and Composition. By Dr. Wilfrid Francis. Pp. viii+567. (London: Edward Arnold (Publishers), Ltd., 1954.) 84s. net.

MANY coal-producing countries are to-day faced with urgent problems concerning their supplies of fuel. Some of these problems relate to the more efficient use of the available supplies of coal; some are concerned with the rapidly diminishing reserves of certain all-important types and the employment, where possible, in their stead of more abundant kinds

The solution of these difficult and varied problems will need the integrated effort and experience of specialists in many fields The role of the fuel technologist is to effect this integration and to translate it into practice in the light of his own specialized knowledge and experience It is therefore a noteworthy occasion when a comprehensive treatise appears on the subject which is the foundation of all fuel technology relating to coal, namely, the formation and composition of the fuel itself

In presenting his book it is the author's intention "to help serious students of fuel technology and coal chemistry in all stages of their work" This he will undoubtedly do, because as the knowledge and experience of the practising fuel technologist widen, he will seek more and more frequently to find the key to the solutions of many of his problems in the constitution of the coal itself

All studies of the constitution of coal must of necessity include considerations of the original vegetable matter from which the coal was formed and of how the various constituents changed, under different conditions of climate and environment, during the transformation into coal. Roughly one-half of the book is devoted to these matters The subject-matter is illustrated by numerous photomicrographs the reproduction of which is beyond reproach except in certain isolated cases where the originals had been published previously by their various authors in a form not suitable for further reproduction Many students will feel, however, that they would have obtained more help from the illustrations if, in some cases, the various plant tissues mentioned in the text had been suitably indicated

The remainder of the book deals largely with coals of the types found in Great Britain and with certain of the methods which have been used for obtaining some insight into the actual chemical structure of the coal substance As the coal matured through the various stages from peat to anthracite, there were accompanying changes in both structure and physical properties Although coals at all stages of maturity are mixtures of the products of transformation of many different types of vegetable entities, their properties in general can be fairly accurately assessed from a knowledge of their elementary composition On this fact are based all systems of practical coal classification Failure occurs only in unusual circumstances It seems to the reviewer that little is to be gained, except possibly in the more strictly scientific investigations, by the adoption of the elaborate system proposed by the author, which is based on the composition of the individual components of the coals

It is somewhat surprising to find no mention of the work of Millott, Cope and Berry in the discussion of Hilt's law Their examination of the coal seams encountered in a deep boring at Pie Rough, North Staffordshire, during a war-time search for oil provided a striking illustration of the truth of the law

Occasionally a statement appears for which there is little or no experimental support For example (p 313), ". . nitrogen and sulphur can replace oxygen in many ring structures with little effect upon the properties of the coal" The problems of coal constitution would be greatly simplified if such a substitution could be made with certainty under conditions where the ring structure of coal was otherwise undisturbed

These are minor criticisms The author has presented to students of fuel technology a book which deserves the highest praise and which will rapidly occupy a place of importance in the literature of the subject L Horton

FURAN, ITS HOMOLOGUES AND DERIVATIVES

The Furans

By A P Dunlop and F N Peters (American Chemical Society Monograph Series) Pp. xix+867 (New York Reinhold Publishing Corporation, London Chapman and Hall, Ltd , 1953) £7 4*s*. net

FURFURAL, accidentally discovered by Dobereiner in 1821 and christened "artificial oil of ants", has to-day become a major commercial chemical. Its rapid rise to industrial maturity during the past thirty years constitutes one of the greatest achievements of chemurgy—the science concerned with the utilization of agricultural waste materials in industrial processes The pioneering work of LaForge on the utilization of corn-cobs, the brilliant researches of Miner and Brownlee on oat hulls and the classic investigations of Mains on the furfural–water system are prominent landmarks in this notable development

A derivative of furan, furfural, by virtue of its chemical reactivity, has become the source of many other important furan derivatives With the advent of cheap and plentiful furfural, its industrial applications multiplied apace, and interest in furan chemistry, both in academic and industrial laboratories, received considerable stimulus So voluminous is the literature on the subject to-day that the compilation of a monograph on "The Furans" was a truly monumental effort The authors, eminently qualified to undertake the task, are to be congratulated on being the first to attempt a complete treatment of this important and rapidly expanding field of chemical endeavour, and the work ranks as a most valuable contribution to chemical literature To keep the monograph within reasonable proportions (as it is, it runs to more than eight hundred pages) some omissions were inevitable Thus, anhydrides, for example maleic and phthalic anhydrides, and γ-lactones which might in one sense be regarded as furan derivatives, and compounds wherein the furan ring is fused to another cycle, are not included, and the hydrogenated furans are only discussed in relation to their commercial importance

Starting with a general review of the chemistry and structure of the furan series of compounds, the authors proceed to a detailed discussion of the chemistry of furan, its homologues and derivatives with halogen, nitro, hydroxy, amino, keto, carboxyl, aldehyde and metallic groups The chapters on furfural, its production, analytical methods, physical and chemical properties are extremely well written This first part of the monograph concludes with a review of the hydrogenation and cleavage reactions of the furan nucleus The second half is devoted to the industrial applications of furfural as a chemical intermediate, industrial solvent and for resin manufacture. Pride of place in the first role goes to the use of furfural for the synthesis of adiponitrile, key intermediate in the nylon synthesis. This use is now the largest single outlet for furfural A propitious combination of physical characteristics makes the aldehyde a valuable and selective solvent, and both furfural and furfuryl alcohol find extensive use in the manufacture of synthetic resins These applications are fully covered and a compilation of patents relating to furan resins is appended

The book has many excellent features and is very well produced It is authoritative, and, within the limits defined, comprehensive It is to be regretted that the high price, possibly justified in the light of present-day production costs and the labour involved in its preparation, will severely restrict the sale of this most valuable treatise J. IDRIS JONES

SCIENCE AND TECHNOLOGY OF TEXTILE FIBRES

Matthews' Textile Fibers

Their Physical, Microscopic, and Chemical Properties. Prepared by a Staff of Specialists under the Editorship of Herbert R Mauersberger Sixth edition Pp. x+1283 (New York John Wiley and Sons, Inc., London Chapman and Hall, Ltd., 1954) £6 12*s* net

IT is just fifty years since the first edition of Matthews's "Textile Fibers" appeared—a half-century that has witnessed the birth and rapid expansion of modern textile research, and the concurrent development of the technology of man-made fibres to its present size and importance As was inevitable, during such a period, a steady stream of revisions has been necessary to keep such a fundamental reference work abreast of the times. The present edition, the sixth, worthily maintains the succession As in the case of its immediate predecessor, it consists of a series of monographs, by distinguished American authors, which together cover the whole field of the textile fibres—natural, artificial and synthetic, their identification, properties, uses and assessment

The weakest section is that devoted to fibre-testing methods, which remains practically unaltered from the previous edition Whereas much of the early testing apparatus described has no modern interest and could have been omitted, no reference is made to the considerable volume of work that has been published on the bending properties of fibres, abrasion resistance, fatigue effects and creep phenomena Of the ninety-five references contained in the bibliography of this section, only eight refer to work carried out within the past ten years There is also a serious double transposition in the text on pp 1245–1247, which should be corrected in any future impressions

In compensation, the section devoted to the microscopical and physical properties of wool, revised to include recent electron-microscopic studies, is excellent, as is also that dealing with the interpretation of X-ray fibre photographs, written for the non-specialist reader This latter section appears for the first time in this edition The sections concerned with man-made fibres have been considerably revised and extended. and, so far as the inevitable delays of publication allow, they are up to date The need for a revision of these sections was, in fact, one of the chief reasons for the present edition, and it has been admirably met

The book is well indexed, and the bibliographies appended to each section greatly enhance its value as a work of reference As "a textbook for use in colleges and technical schools" in Great Britain, its strongly American flavour, inevitable in view of the general authorship, is a decided disadvantage Nevertheless, it will continue to be used for reference purposes, in the future as in the past, because of the scope and competence of its contribution to textile knowledge

BIRATIONAL GEOMETRY

Methods of Algebraic Geometry

By Prof W. V D Hodge and Dr. D Pedoe Vol 3, Book 5 Birational Geometry Pp x+336 (Cambridge At the University Press, 1954) 40*s* net

THE scope of this book is more restricted than might have been expected from the title It does not deal with birational geometry as a whole, for the fundamental properties discovered by the great Italian geometers have been entirely omitted The reason for this is explained in the preface The authors' intention is to explain methods, not results or a unified theory, and not all methods, but only those based upon the modern abstract algebra of rings, ideals and valuations These methods are largely due to the recent work of O Zariski The reader is assumed to be already versed in the ordinary methods of algebraic geometry On the other hand, no knowledge of abstract algebra is assumed, beyond that contained in the earlier volumes It is a great convenience that the geometer will find in this volume and the earlier ones all the algebra he needs, though it entails that nearly half of this volume is algebra rather than geometry

This volume contains four chapters The first deals with the theory of ideals in a commutative ring, including prime and primary ideals, remainder-class rings, subrings, extension and quotient rings, modules, multiplicative theory of ideals, and integral dependence The second chapter deals with the arithmetic theory of varieties and applies the results of the first chapter to geometry Great stress is laid upon projectively normal varieties, which are used extensively in the more advanced parts of birational theory The third chapter deals with the concept of abstract algebra known as the valuation of a function field This generalizes the classical theory of a branch of an algebraic curve, and is of fundamental importance in the theory of birational transformations The authors point out that many of the results could have been obtained more simply and elegantly by Weil's method, using what are called specializations However, it is unlikely that a complete theory of birational transformations can be built up without valuations, so geometers should study this method Valuation theory can also be applied to the theory of numbers, but the account here is restricted to what is required for geometry

The fourth and last chapter is entitled "Birational Transformations" Most of it is devoted to problems concerning multiple points A problem still unsolved is whether we can obtain, for every algebraic variety, a birational transform without multiple points. Some light is thrown upon the structure of multiple points by Zariski's local uniformization theorem No less than seventy pages are devoted to the proof and applications of this fundamental theorem The volume concludes with two pages of bibliography and bibliographical notes, and an index.

H. T H PIAGGIO

SCIENCE AND ADULT EDUCATION

THE ROLE OF THE UNIVERSITY EXTRAMURAL DEPARTMENT

By DR. H. D. TURNER

University of Sheffield

IT is extremely difficult to define clearly the aims and purposes of adult education. This is due partly to the number of different activities and subjects which it embraces, partly to the various ends which it is designed to serve, and partly to the number of organizations concerned in its provision. A precise definition of science in adult education is impossible for similar reasons.

The general case for the inclusion of science as a humane study in adult education has been well stated by Peers[1] in his report to the Universities Council for Adult Education. There are, however, other equally important aspects of science and technology with which extramural departments may be usefully concerned, and it is at least arguable that teaching in these fields is one of their proper functions.

The following list includes most of the activities which, collectively, may be regarded as constituting science in adult education.

(1) The teaching of separate subjects such as biology, chemistry, physics and geology. These may be presented at various levels ranging from the most elementary introductory lectures to descriptions of recent advances.

(2) Courses, at various levels of presentation, in all branches of technology.

(3) Lecture series in the history of science and technology.

(4) Discussion of the impact of science and technology on society.

(5) Groups of special lectures in science and technology which may, for example, supplement normal courses in history and economics.

At the moment there is a general tendency, reinforced by the conclusions of Peers, to suppose that at the advanced level (1) is too difficult and at the elementary level is outside the scope of extramural departments; that (2) is not the concern of extramural departments; that (3) is unpopular and hence not worth attention; that (4) is not science and therefore not suitable for inclusion in science teaching; and that (5) is better done by the appropriate specialist.

We may say at once that (1) and (2) should, at the elementary level, be provided by local education authorities; and that, in the main, the problems raised by the impact of science and technology on society should be of interest to the Workers' Educational Association, since these problems are similar in origin and effect to those which stimulated the early development of the Association.

Many successful courses of the type included under (1) above have been given at Sheffield during the past six years. The Extramural Department has usually arranged and administered the courses, while the lecturing has been done by internal members of the University staff. The form of such courses must always be adapted to the requirements of potential students. For example, lectures and demonstrations on recent advances in various sciences are probably best given as one-day Saturday courses, since this is often a free day for graduates in teaching and in industry; but such provision should be supplemented, where possible, by longer residential courses. These, although more difficult to organize than evening lectures, offer great advantages; demonstrations and practical work are more easily provided, and the opportunities afforded for discussion and general social activities enormously enhance the value of the course. It is not difficult to believe that such residential courses may well become one of the most important features of adult education in the future. Sometimes, however, it may be necessary to stimulate interest in a subject, and form a class, by a series of progressive courses as, for example, in recent developments in the teaching of geology. A single public lecture had shown that a certain amount of interest existed in a particular area. This lecture, therefore, was followed by a short course on local geology which was so successful that it led to a longer course (of twenty meetings) on "The Scenery and Resources of Britain". From this has developed an intensive study course, attended by twenty-five students, which covers much the same ground as the first-year course in geology at the University; and this sequence is being increasingly used for the development of courses in other subjects. Courses of this type are generally restricted to the University and to large centres of population. In these the Department frequently organizes courses in co-operation with the local technical colleges, where adequate lecture rooms and reasonable facilities for practical work and demonstrations are normally available. Thus these educational needs of adults in the areas are provided by the resources of the technical college supplemented where necessary by those of the University.

Most universities have technological departments which often serve both local and national industry. There have been many interesting developments in these departments, such as the establishment of post-graduate schools of study, which are organized without the help of extramural departments. At the same time, the extramural department, with its contacts in industrial and educational circles, may often be able to advise in the provision and help with the organization of many worth-while courses, the need for which is not always immediately obvious. For example, at Sheffield the Extramural Department, in co-operation with the Departments of Metallurgy and Fuel Technology, has started a series of very successful advanced residential courses in "Fuel and Metallurgical Problems of Jet Engines" for engineer officers in the Royal Air Force; and there are obviously many similar fields in which the Extramural Department can pioneer new developments of mutual benefit to the Services, the university and industry.

Courses in the history of science and the history of technology are, unfortunately, rarely included in any educational scheme. There are many reasons why the universities should sponsor the teaching of these subjects. Their staffs include the necessary specialists with the requisite facilities. The history of science and technology covers ground that is common to the arts and science; and the problems of liberalizing science courses and of interesting arts students in science may be solved by courses in these subjects.

Experience in the field of extramural studies shows that there is considerable interest in such topics and in the philosophy of science. A number of experimental courses in the history of science have been given, and in these the 'case-book' method developed by J. B. Conant at Harvard University[2] has been used and considerably extended. In the most successful courses various important experiments in the history of science, such as the analysis of light, the discovery of oxygen and the discovery of the electron, have been described and demonstrated, and their scientific and technological consequences discussed. One surprising feature of these lectures has been the large attendance of senior sixth-form grammar school pupils.

It has already been suggested that courses on the impact of science on society might very well be suitable for the Workers' Educational Association. Such courses have been given at the request of local Association branches; but generally the response has been very poor. Very much more could and should be done in this field; a technological society is obviously extremely unstable if its members are ignorant of and uninterested in technological developments and the problems which these pose.

There are certain parts of courses in history and economics in which contributions from scientific specialists are essential. Only a scientist can adequately assess the influence of scientific discoveries on the climate of scientific opinion and on technological development. Such experience as we have had indicates that, provided problems of continuity can be solved, joint extramural courses by, for example, a historian and a scientist are very successful.

Certain general conclusions may be drawn from what has been said above. For example, it seems desirable that extramural staffs (at any rate in science) should be primarily advisers and organizers, although they should obviously keep in touch with their subjects by research and by internal and external teaching. This means, of course, that the bulk of extramural science teaching will be done by internal members of university staffs. The university, however, has obligations to the community in which it is situated, and to the tax-payer who nowadays largely finances it. The discharge of such obligations may very well involve, among other things, the explanation of the nature, purpose and results of the research work which is being done by universities.

Although extramural departments should be prepared to co-operate with all who seek their help, their main concern should always be with the provision of courses, delivered at a university level, for those who are capable of benefiting from them. In practice, these will probably be ex-grammar school people whose spare time is often limited. Hence, much of this provision must be in the form of short intensive one-day, week-end or residential courses and series of, say, not more than six evening lectures.

The activities of extramural departments should be widely known and this means that extensive advertising of courses is necessary. This has the additional advantage that students recruited to an advertised course form a reasonably homogeneous group.

The extramural department should, at this time, be encouraged to investigate every possible field of activity open to it. Experimental work and courses of all kinds should be tried; and this means that its activities should not be artificially restricted by financial straitjackets or by out-worn regulations. For example, sixth-form grammar school students are not officially admitted to extramural lectures and classes. Yet they are adult; they are capable of absorbing information at the appropriate level; they are prepared to turn up voluntarily in large numbers for lectures on the history of science and on modern scientific and technological developments; and they are the extramural students of to-morrow. If they are encouraged to-day to look to the university, through its extramural department, for their further cultural education, the problem of recruitment to classes in the future may very well solve itself.

There can be no doubt that in order to achieve all this it will be necessary for extramural departments to be directed solely by the university council and senate working through appropriate committees. This would give the departments the necessary status and flexibility of approach; and the obvious corollary to this is that the money required to finance their activities should be provided by the University Grants Committee as for other university departments.

RADIATION HAZARDS IN INDUSTRY

THE third conference of the British Occupational Hygiene Society was held on November 1 in the lecture theatre of the London School of Hygiene and Tropical Medicine, the subject of the conference being a consideration of the radiation hazards in industry. The chair was taken by Prof. E. J. King (Postgraduate Medical School of London). The subject was originally introduced at the second conference of the Society held in April 1954 when Dr. W. G. Marley (Atomic Energy Research Establishment, Harwell) delivered a paper on the permissible levels of exposure to ionizing radiations and radioactive materials. In this paper Dr. Marley discussed the basic 'tolerance' level or maximum permissible level for X-rays or gamma-rays, and then proceeded from the basic 'tolerance' for X-rays and gamma-rays to calculate the permissible exposure to various types of radiation, allowing for their relative biological effectiveness. Similarly, the maximum permissible body-burden of radium is a valuable starting-point for the calculation of maximum permissible levels of different radioactive isotopes taken into the body. Dr. Marley described the method by which international agreement on maximum permissible levels has been reached. The experience of the atomic energy departments and of radiobiological specialists in the United States, Canada and the United Kingdom has been compared in a series of tripartite conferen[illegible] commencing in 1949. Since then, data have been considered by the International Commission on Radiological Protection during the meetings of the International Congress of Radiology in 1950 and

1953 The third conference of the British Occupational Hygiene Society therefore started with a knowledge of the maximum permissible levels and with the assurance that they are internationally agreed levels

Dr A S McLean (principal medical officer of the Industrial Group, United Kingdom Atomic Energy Authority) opened the third conference of the Society with a paper on the health of workers exposed to ionizing radiation He referred to the history of man's use of atomic energy since the turn of the century up to the present time, when he has learned to exploit it on a grand scale. Dr McLean was less concerned with the effects of massive doses of radiation than with the pattern of injury which may be the outcome of long-continued exposure just above the critical level for these effects The consequences of chronic over-exposure have been seen in several groups of human beings, including painters of luminous dials, miners of radioactive ores, and pioneer workers in the scientific and medical fields , in addition, there has been a vast amount of experimental work with animals From these observations it is known that the sensitivity of any organ of the body to the effects of irradiation is generally a function of the rate of cellular activity in that organ, so that the blood-forming and reproductive tissues, for example, are more easily damaged than the nerve tissue of the brain Nevertheless, a tissue of relatively low sensitivity may be damaged exclusively when it is the site of selective localization of a radioactive substance which has entered the body. Thus, radiation protection contains two distinct problems which are concerned with the irradiation of whole or part of the body from the outside and with the irradiation of selected organs of the body following uptake of a radioactive substance by breathing or by swallowing Dr McLean discussed both these problems and listed the main body organs involved Of particular interest to the medical officer is the detection of radioactivity in the excreta , but since in some cases this involves the determination of micro-micro-gram quantities of radioisotopes, the radiochemistry involved is not easy Dr McLean concluded with a review of the comprehensive medical facilities which are used in the selection of workers and in the maintenance of health in the workers employed in the atomic energy industry

The second paper, dealing with radiation safety in the Industrial Group of the United Kingdom Atomic Energy Authority, was by Mr. D R R Fair (head of the Health Physics Department, Windscale Works, Sellafield, Cumberland) He reminded the audience that, in thinking of radiation safety in industry, they must not think of scientists working in laboratories but of factory managers employing process workers and skilled craftsmen working in factories He discussed external irradiation and the design office's contribution to the safety of the worker in the provision of radiation shields and the layout of plant and equipment to make use of distance for safety

The contribution by works management to safety is called for when plant has to be maintained or modified A decision has to be made whether to postpone operations in order to allow short-lived fission products to suffer radioactive decay or whether the radiation field may be reduced by decontamination of the plant Before work commences, management has to decide whether local radiation shielding must be built, the workers have to be briefed on the method and sequence of work they are to carry out, and the time the worker is in the radiation field ha to be carefully controlled Mr Fair then turned t the harder task of the atomic energy industry, th protection of the worker from the inhalation c ingestion of radioactive materials The design office have provided all-welded plant using a speciall corrosion-resistant stainless steel, liquid transfe mechanisms by hypodermic needle, and adequat ventilation of working space with controlled directio of airflow and proper facilities for the workers t maintain the highest levels of personal hygiene. Th management exercises safely control during mai tenance work by reducing air contamination to minimum, controlling both the volume of air whic is contaminated and its disposal, and by providin the worker with clean air and full head and bod cover while he is on the job Mr Fair discussed i some detail the methods by which managemer achieves these aims He concluded by reviewing th position and responsibilities of the health physici in an atomic energy works

Mr W Binks (Radiological Protection Service (the Ministry of Health and the Medical Researc Council) presented the third paper, and dealt wit protection against X-rays and gamma-rays in th industrial field He was particularly concerned wit radiation hazards in ordinary industries Exper mental data were given on the direct radiation outpu from X-ray tubes and from radioactive isotopes, o the degree of scattering produced under differer conditions and on the absorption of both direct an scattered radiation in materials such as lead, bricl concrete and soil Mr Binks discussed in detail th solution of a number of problems encountered i designing an industrial radiological establishmen Since the safety of personnel working with ionizin radiations depends as much upon adherence t particular techniques as upon the provision (structural shielding, Mr. Binks included details (the various monitoring techniques which may b adopted to assess the actual dose received by worker Finally, he described the help which it is anticipate the Radiological Protection Service will give t industrial managements in designing radiologic establishments and in carrying out radiation surve and personnel monitoring tests.

The final paper at the conference was by M F R Farmer, assistant director, production, (the Industrial Group, United Kingdom Atom Energy Authority, Risley, who dealt with the safet criterion in atomic energy Mr Farmer made review of the hazard-level in industry as measure by the death-rate and compared this in the workin population age-group with the death-rate due t natural causes and to violence He quoted deatl rates of 10–12 for normal industry, 30 due to violenc (including 12 on the roads), 80 for the mines and 14 due to natural causes, all per 100,000 In a civilizatio with a rising standard of living, changes in the publ attitude to such figures may be expected and demand will arise for preventive action to be take

Mr Farmer posed the problem of the new industr and asked what should its objective be While it ma be argued that a zero risk is highly desirable th in the absolute sense, is not obtainable It seen reasonable to set as a target for a new industry th it must be comparable with the best in other indu tries Looking back over other industries, it probable that safety has been influenced by the nee of the industry to sell its products economically in competitive market, and the cost factor in safet must not be lost sight of if the atomic energy industry is to make its mark in the national economy. Mr. Farmer concluded that the safety aim of the atomic energy industry must be for perfection within an economic framework that will encourage the development of the industry.

Each paper presented to the conference was followed by a period of full discussion in which many points of principle and some of detail were discussed. It was agreed that the safety-level established in the atomic energy field compares very favourably with much of established industry, but that a larger experience of radioactive work in industry will be needed before final conclusions can be drawn.

D. R. R. Fair

RESEARCH ASSOCIATION OF BRITISH RUBBER MANUFACTURERS

OPENING OF NEW LABORATORIES NEAR SHREWSBURY

On November 23 H.R.H. the Duke of Edinburgh officially opened the new laboratories and headquarters at Shawbury, near Shrewsbury, of the Research Association of British Rubber Manufacturers. Some three hundred persons were present, drawn from all sections of the rubber and allied industries, together with representatives of government departments and other organizations connected with the rubber industry, and after the opening they were able to visit the premises and inspect the displays showing various aspects of the Association's work. In his speech to the company the Duke referred to the obligations of industry towards co-operative research and its results, and put in a strong plea for yet more generous financial support by industry of the Association's work. He also stressed very much the problem of getting a research association's results applied in industry—"probably the most complicated and elusive problem confronting the industry to-day".

The ceremony formed a fitting and stimulating climax to the efforts that have been made during the past years to provide the Association with premises adequate for its growing needs. Founded in 1919, the Research Association of British Rubber and Tyre Manufacturers (as it was first called) began work in two rooms in University College, London, and then in 1922 premises were acquired in Lansdowne Road, Croydon. For many years these met the Association's needs; but the very success of its work, and especially the demands made on it during the Second World War, led to an expansion that seriously overtaxed the available space. By 1948 it became clear that the only solution was to find entirely new premises, and bearing in mind that the 'centre of gravity' of the rubber industry lies in the Midlands rather than the London area, the Council of the Association decided, after exhaustive inquiries and searches, to acquire premises already existing at Shawbury. These were purchased in January 1952, and since then the task of adapting them has proceeded steadily. Now that task is complete and the premises have been officially opened, the industry possesses a research station of excellent design, attractive in external appearance and interior finish, and fully equipped for the important work that lies before it.

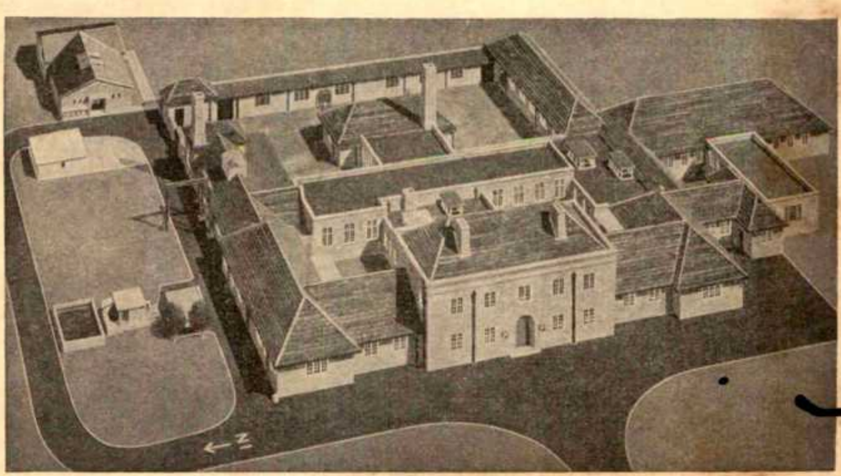

Fig. 1. Aerial view of new Laboratories of the Research Association of British Rubber Manufacturers

The new premises (Fig. 1) are near the village of Shawbury, 6½ miles north-east of Shrewsbury on the Market Drayton Road (*A* 53). Erected in 1938 by Shropshire County Council, they have a floor area of some 15,000 sq. ft. and stand on a level site of about 6½ acres. The whole building is on one floor, except for two flats over the front portion. Although built for a different purpose, the lay-out has proved surprisingly convenient for the laboratories, library, workshops and offices of the Research Association.

The laboratories proper are grouped into three categories: chemistry, physics and technology. The chemical laboratories are in two groups. In the first, the main laboratory is for analytical work, including the testing of raw materials, analysis of vulcanized rubbers, identification and estimation of synthetics, and so on, and has for this purpose many pieces of specialized apparatus. The equipment includes also a micro-balance, used in developing micro-chemical techniques applicable to rubbers and other polymers, a Spekker absorptiometer for colorimetric analyses, and an infra-red spectrometer which has been devoted particularly to the identification of organic accelerators and antioxidants in vulcanized rubbers. Other laboratories are fitted up for studies on adsorption of simple hydrocarbons on carbon black and other powders, as part of the research on the mechanism of filler reinforcement. The second group includes the main chemical research laboratory, at present devoted largely to studies on copper (and other heavy-metal) catalysis of oxidation and the development of improved sequestering agents for combating the effect of copper in promoting oxidative deterioration (ageing) of rubber.

The physics laboratories comprise two large adjacent rooms, one of which is devoted mainly to electrical measurements and has a full range of equipment for studies of volume and surface resistivity, permittivity and power factor, as well as special apparatus for testing the electrical characteristics of 'anti-static' rubber, a subject to which the Association has made important contributions. High-voltage equipment is housed in the adjoining laboratory, which also deals with studies on plasticity, using in particular the Association's 'shearing-cone plastimeter' and various other types (Fig. 2). In this room also is installed the new sinusoidal-strain dynamic testing machine constructed to designs worked out by the Association, and which will enable more complete studies of the dynamic behaviour of vulcanized rubber to be undertaken than have hitherto been possible.

The technological laboratories include the mill room, equipped with up-to-date experimental mixing plant (both open-roll and internal types) and vulcanizing equipment (platen presses and open-steam pan); and the mechanical testing laboratory, which possesses a full range of instruments for examining the physical characteristics of vulcanized rubbers—strength, extensibility, 'set' or residual deformation, hardness, resilience, resistance to tearing and to abrasion, behaviour at low temperatures, etc. (Fig. 3). These instruments, particularly those for testing hardness, include several designed by the Association or by member firms on the basis of studies by the Association. Auxiliary laboratories contain equipment for testing the resistance of rubber to repeated flexing and to the deteriorating actions of heat, oxidation, light and atmospheric ozone. This technological equipment enables the research staff to prepare experimental rubber samples under carefully controlled conditions and to assess their properties and likely behaviour during use.

In addition to these various laboratories, the premises include the library and information section, or Intelligence Division, as it is called. This contains what is believed to be the world's largest library on rubber and cognate subjects such as rubber-like plastics, together with card indexes, now totalling some 750,000 cards, on which scientific, technical and commercial information on rubber is arranged in classified order for easy reference in answering inquiries and preparing literature surveys. Offices for typing and duplicating work, a photographic dark-room, an engineering workshop, and a spacious canteen complete the layout of a research station of which the rubber industry may well feel proud.

TREATMENT AND DISPOSAL OF SEWAGE SLUDGE

SINCE methods of treating water-borne sewage were first adopted in Britain, it has seemed obvious to many people that it should be possible to utilize profitably the plant nutrients which the liquid contains. That it is at least difficult to do this, and at the same time to dispose of the material without causing a nuisance or endangering public health, became clear during the second half of the past century when most of the sewage in inland districts was disposed of by irrigation on 'sewage farms'. For various reasons this method fell into disrepute—large areas of land were needed; land is usually expensive near towns, where most of the sewage is produced; the soil must be porous to permit irrigation at a reasonable rate; the sewage is produced continuously, but the farmer prefers to take it for irrigation only intermittently. Most sewage farms have now been replaced by modern, compact treatment plants which, at a remarkably low cost, are capable of converting sewage—often containing a large proportion of industrial wastes—into effluents which can be discharged to the small streams of Britain without serious risk to public health. The possibility of maintaining this position, but at the same time recovering further useful materials from sewage, is, however, still often raised Suggestions include using sewage effluent for irrigation, sometimes by distribution from overhead sprinklers, passing it through fish ponds, and using it as a nutrient medium for growing algae which would be harvested and dried It was because of this widespread interest in the use of urban wastes that the Natural Resources (Technical) Committee, under the chairmanship of Prof S Zuckerman, decided recently to publish the results of its study of the subject[*]

In the processes of treatment ordinarily used at a sewage works, as much insoluble material as possible is first separated by sedimentation, yielding a primary sludge containing perhaps 90–97 per cent of water The remaining liquid is then treated by a biological process to give an effluent, which is usually discharged to a stream, and a secondary sludge of high water content For every thousand persons there will be perhaps ten to twenty million gallons of effluent a year, with sludge containing twenty-five tons of dry solids

Of the inorganic nutrients present in the raw sewage, a large proportion, including most of the potash and about three-quarters of the nitrogen, is discharged with the effluent, from a thousand persons the weight of nitrogen lost annually is of the order of two tons The Natural Resources Committee recommends that methods of sewage treatment which would conserve the nutrients now lost in effluent should be investigated, so far as is known, no generally applicable methods are at present available, except that in arid countries sewage effluent is valuable for irrigation, much of its value being represented by its water content

It is much easier, however, to make use of the sludge separated at a sewage works, and indeed it is estimated that the equivalent of some 350,000 tons dry material (containing some 8,000–9,000 tons nitrogen (N), 4,000–5,000 tons phosphate (P_2O_5), and 1,000 tons potassium (K_2O)) is at present applied to the land annually in Britain as manure This is rather more than a third of the total which could be made available from the present sewered population of about 39 million persons, of the other two-thirds, part goes to sea, either in suspension where untreated sewage is discharged (as in Liverpool) or in tank steamers after separation on shore (as in London), and part is ultimately stored in tips at sewage works

The chief difficulty in disposing of sewage sludge, whether for agricultural or other uses, lies in drying it to a moisture content at which it can be transported economically and handled easily Several methods of drying are used, and it was known that the efficiency and cost of the process differed widely at different sewage works. A committee was therefore set up by the Ministry of Housing and Local Government to study the question, and it has now issued a most interesting report[†], from which the following brief notes are taken

The weight of sludge produced per thousand persons annually may range from ten tons in a rural district to more than eighty tons in an industrial one—clearly the composition of the sludge will vary equally widely The price at which partially dried sludge can be sold (per ton dry weight at the works) ranges from nothing (air-dried to 65 per cent moisture) to more than £6 (digested, 15 per cent moisture, powdered and bagged) Digestion—that is, anaerobic fermentation to yield methane and carbon dioxide—is already in use at many large sewage works, the Committee recommends the extension of the process to smaller works. Of the more mechanical drying processes, filter pressing, vacuum filtration and filtration after heating are practised at a few works, but centrifuging, though used in the United States, has not been tried in Britain A serious drawback of some of these methods is that the liquid which separates may contain a high concentration of organic matter and may add appreciably to the load on the biological stage of the sewage treatment plant An interesting and effective method of drying consists in adding a coagulant, freezing and thawing the sludge, and then filtering, large-scale plant, however, has not yet been developed, and the economics of the process are uncertain Electro-osmosis, already in use for drying soils in engineering work, appears to be inherently too expensive to use with sewage sludge

After reviewing these various methods, the committee finds in favour of the simple and unmechanical, its choice of methods being in the following order disposal in a liquid form, preferably after digestion, to manure agricultural land, digestion, and drying to 40–50 per cent moisture on beds or in lagoons, drying to 10 per cent moisture content after careful consideration of the possibilities of marketing the product, and finally—chiefly in rural areas—composting with other waste materials such as separated household refuse

This report is valuable in giving an up-to-date and balanced account of the practice of sludge treatment in Britain, it will lend little support to the theory, so often put forward, that there is in sewage sludge a large unused source of nutrient materials which could be made available to agriculture without much difficulty if only the problem were energetically attacked

OBITUARIES

Prof H Terrey

THROUGH the death on Christmas morning of Prof Henry Terrey, a loss has been sustained which will be felt in many departments of the academic life of the University of London, and in every phase of the life of University College Prof Terrey had been continuously associated with the University and with the College since 1912, successively as student, assistant, lecturer, reader and professor, and after his retirement from his University chair in September 1954 he had continued to serve the College by maintaining without interruption the discharge until the day of his death of the duties which had been his as a professor

Terrey was one of that somewhat rare species at the present time, the true-hearted inorganic chemist, though with a well-assimilated knowledge of the principles, practice, and the helpful applications of physical chemistry and a general working knowledge of organic chemistry For many years he had been the leader and mainstay of inorganic chemistry in a comprehensive chemical department in which the balance of interest between the branches has not always been easy to maintain But Terrey was of the view that the best answer to that problem was.

to have no incommutable branches and no boundaries, and the breadth of his general chemical knowledge, widely outside the orbit of his personal researches in the chemistry of the rarer elements and some other special fields, as was often shown by his regular and active participation in all discussions of researches in progress, fitted him well to put such policy into practice. His specialized knowledge of the factual basis of general and inorganic chemistry was unsurpassed.

It is impossible to overstate the value of his personal qualities to the University of London and to his College. Well adjusted, friendly and wise, he was the man to whom, even when he was still a lecturer, students and professors alike turned to naturally to talk over their difficulties, knowing that they would probably come away with practical help of one kind or another, and certainly with an easier mind and a clearer course of action. He was much interested and gave much help in the organization of students' athletic activities. His personal knowledge of students throughout the years was remarkable, and for a long period he gladly gave his time to the furtherance of the affairs of the Old Students' Association of University College. His qualities cast him for the role of chairman of many boards and committees, the business of which, however contentious, he always kept on the plane of good sense and good humour. In all personal relations, his academic life was a kind of extension of his very happy home life, in which he was husband, father and grandfather. He took little, and gave much, and we who are left will gratefully revere his memory.

Mr. F. B. Stead, C.B.E.

It is with very deep regret that his former colleagues and friends learnt of the death of Mr. F. B. Stead on December 23. He was born on February 19, 1873, the son of the Ven. Samuel Stead, formerly Archdeacon of Bombay. He was a boy at Clifton College, going from there to King's College, Cambridge. At Cambridge he was placed in the first class of the Natural Sciences Tripos and left to become an assistant master at Aldenham School in 1898. In 1901 he returned, as assistant master, to his old school and remained there until 1908. He was made head of the chemistry department at Clifton College in 1908, but left soon afterwards on being appointed one of His Majesty's Inspectors of Schools, an office he occupied for the next twenty-five years, until he retired in 1933.

Stead was made staff inspector on appointment and served in Essex, Surrey and Kent. During the First World War, after being temporarily in charge of Hampshire, he transferred to the Ministry of Munitions. During 1916–18 he acted as secretary to the Prime Minister's Committee on the Teaching of Science, under the chairmanship of Sir J. J. Thomson. After the War he became a divisional inspector of education for seven years, and in 1926 was appointed chief inspector and took charge of the Secondary Branch, then responsible for the inspection of the grammar schools. He was made C.B.E. in 1931. After retirement from the inspectorate he continued for some time as an occasional inspector and even returned to full-time employment for a few months in 1940. He was chairman of the Girls' Public Day School Trust during 1944–48 and since then had been deputy chairman.

One of the most remarkable features of the educational history of Great Britain was the extremely rapid development of grammar school education during the first third of this century. In that development the Secondary Branch of His Majesty's Inspectorate, created shortly after the coming into force of the Act of 1902, played a part the importance of which has not been fully appreciated. Stead joined that Branch early in its history, and seldom was a wiser appointment made. In the first place, not only was he distinguished as a scientist, but also, even more important in view of the work to be done, he was a man of broad general culture who fully realized the dangers of early specialization which beset so many schools in that period. Secondly, sincere and forthright as he was and impatient of loose thinking and sentimental aspirations which so easily beset new developments in education, he was quick to encourage enterprises based on common sense and long and careful study of a situation. Because of this and because of his courage and unselfishness and his immediate and generous recognition of good work wherever he found it, he won the lasting respect and affection, not only of his colleagues, but also of all—administrators, governors and teachers—with whom he had to deal in his twenty-five years of public service.

NEWS and VIEWS

Electrical Engineering in the Imperial College:

Prof. A. Tustin

The appointment has been announced of Prof. Arnold Tustin to the newly created University chair of heavy electrical engineering in the Imperial College of Science and Technology, University of London. The appointment carries with it the position of head of the Department of Electrical Engineering in the College and is of especial importance in view of the plans for the expansion of the Imperial College, which have already been widely announced. Financial support has been provided for this chair from the Counterpart Aid Funds. It is intended that the chair of electrical engineering, recently vacated by Dr. Willis Jackson, shall be filled as soon as practicable by a professor of light electrical engineering within the Electrical Engineering Department of the College. Prof. Tustin, who is at present professor of electrical engineering in the University of Birmingham, is well known for his work on automatic control systems and in other fields. He has recently spent a year at the Massachusetts Institute of Technology studying the teaching of engineering, which is one of his many wide interests.

Chemical Engineering at Swansea

Prof. E. S. Sellers

Mr. E. S. Sellers, whose appointment to the newly established chair of chemical engineering in the University College of Swansea has recently been announced, is a graduate of the University of London.

He was first employed in the Lancashire textiles industry and later by the then Anglo-Iranian Oil Co. at Abadan Mr Sellers returned to Great Britain in 1938 and joined the staff of the Manchester Oil Refinery, Ltd, and was its refinery superintendent at the time of his appointment in 1948 to a University lectureship in the then newly established Department of Chemical Engineering at Cambridge Mr Sellers had previously had some experience of teaching as a part-time lecturer at the College of Technology, Manchester, and from the start was able to play a large part in the planning of the courses and the general organization of the Cambridge School. His research interests have been mainly in the field of distillation processes, including processes operating at very low temperatures Mr Sellers has been an active member of the Institution of Chemical Engineers, being on both its Board of Examiners and its Education Committee He has also been much interested in furthering the co-operation of industry with universities in matters of education, and in the past few years has run two successful 'practice school' courses, first at the Stanlow Refinery of the Shell Refining and Marketing Co, Ltd, and secondly at the Royal Ordnance Factory, Bridgwater It is expected that he will take up his new duties at Swansea next October

Geological Society Awards for 1955

THE Council of the Geological Society has made the following awards for 1955 *Wollaston Medal* to Sir Arthur Trueman for his outstanding and varied contributions to palæontology and stratigraphy and in particular for his palæontological work on the non-marine lamellibranchs of the Coal Measures, this latter work has initiated and led to fundamental advances in palæontology and to the rationalization of British Coal Measures geology, *Murchison Medal* to Dr C J Stubblefield in recognition of his valuable contributions to palæontology and for his work on palæozoic stratigraphy, *Lyell Medal* to Mr W N. Edwards, keeper of geology in the British Museum (Natural History), in recognition of his distinguished work in the palæobotanical field, *Bigsby Medal* to Dr P E Kent for his contributions to the palæogeography and stratigraphy of England and Wales and his researches in Central Africa and Persia, *Wollaston Fund* to Mr J M Edmonds for his contributions to the history of geology and the geology of the Oxford district, *Murchison Fund* to Mr R Casey for his illuminating work on the Aptian and Albian strata of southern England, a moiety of the *Lyell Fund* to Dr P A Sabine for his petrological work, especially in the Assynt area of Scotland, another moiety of the *Lyell Fund* to Dr W Bullerwell for his work in applied geophysics and in particular for his contributions to the gravimetric survey of Great Britain

Royal Astronomical Society Awards

THE following medal awards of the Royal Astronomical Society have been made *Gold Medal,* Prof Dirk Brouwer, director of the Yale University Observatory, for his outstanding contributions to celestial mechanics, *Eddington Medal,* Prof H C van de Hulst, of the Observatory, Leyden, for his prediction of the 21-cm line radiation of neutral hydrogen, and for his share in its detection and observation and in the theoretical interpretation of the observations.

Some Exhibits in the Cavendish Laboratory Museum

AN illustrated account of some of the instruments made by Elliott Brothers, Ltd, which are in the Museum of the Cavendish Laboratory, Cambridge, has appeared in the *Elliott Journal* (2, No. 1, 1954). In an earlier article in the same journal (1, No. 1, 1951) reference was made to some of the apparatus constructed for Maxwell, Rayleigh and others by the firm, but a recent rearrangement of the apparatus in the Museum has suggested a fuller account of the more notable Elliott instruments collected there Maxwell's colour top and his real-image stereoscope are described, and some interesting details are given of his experiments and results using the well-known disk apparatus for the determination of the viscosity of gases, which was constructed for him by Mr Becker and described in Maxwell's Bakerian Lecture to the Royal Society on February 8, 1866 Maxwell was succeeded as Cavendish professor by Lord Rayleigh, whose research was concentrated on the provision and maintenance of high-precision electrical standards Elliott Brothers made some of the earliest sub-standard resistance boxes calibrated in terms of the British Association ohm, and later assisted in the re-determination of the ohm by Lord Rayleigh and Mrs Sidgwick by constructing the well-known spinning-coil apparatus used in that series of experiments A photograph of the apparatus and references to the original papers are included in the article.

Geological Background of the Iyatayet Site, Alaska

IN 1951 Giddings published his discovery of a blade, core and burin industry, which he called the Denbigh flint complex This preceded and differed fundamentally from the known Eskimo occupations of Alaska, including the palæo-Eskimo one of which Ipiutak is a part, and its importance is due not only to its age but also to its possible Upper Palæolithic ancestry A description of the recent geology of the site of the discovery, with an attempt to correlate it with recent deposits elsewhere in Alaska, has been published as a paper by D M Hopkins and J L Giddings, jun, in Vol 119, No 2 of the Smithsonian Miscellaneous Collections (Pub 4110. Pp ii+33+4 plates Washington, D C. Smithsonian Institution, 1953) On archæological grounds, the authors believe that the industry is older than the related one, lacking burins, found at Trail Creek, Seward Peninsula, and dated by radiocarbon at about 4000 B C Two alternative correlations are suggested one would give the Denbigh industry an age greater than 10,000 B C, and the other, which the authors prefer, would date it at about 6500 B C. The paper illustrates the specialized knowledge required for the interpretation of Quaternary geology in these regions, since it includes such unexpected features as the correlation of forty feet of aggradation in a valley with a period of low rather than high sea-level.

Nitrogen Metabolism of Ripening Fruit

IN a recent study of the nitrogen metabolism of apple fruits, A. C Hulme (*J Exp. Bot*, 5, No 14, 159, 1954) has found that a close parallelism occurs in the trend of respiration-rate and the ratio protein nitrogen/non-protein nitrogen, both in attached fr[illegible] and in fruits harvested at various stages of development and stored for several months at 12° C. In detached fruits the fall in respiration which occurs immediately after picking is only accompanied by a concomitant fall in net protein in very young fruits in which active cell-division is taking place Afterwards, in fruit of all ages, when a climacteric rise in respiration occurs, it is accompanied by a net increase in protein It is argued that the climacteric rise in respiration is a result of increase in the level of protein which will be expected to reduce the adenosine triphosphate/diphosphate ratio Over the climacteric period, although rate of respiration and net protein content both rise, the former rises more rapidly than the latter and, afterwards, falls at a faster rate than the protein content It is suggested that this may be due to the 'new' protein containing a higher proportion of enzyme(s) directly involved in respiration and leading, for example, to a reduction in the adenosine triphosphate/diphosphate ratio

Ophioglossum Organization in Embryos and Induced Buds Compared

When the sequence and rate of organ formation in embryos and induced buds of *Ophioglossum vulgatum* are compared, some interesting results emerge (C W Wardlaw, *Ann Bot*, 18, 72, 397, 1954) In the embryo, the appearance of the primary root considerably precedes the organization of the shoot apex and the formation of the first leaf, but in induced root and shoot buds the reverse is the case With the limited nutrition provided by the saprophytic underground prothallus, the first leaf of the embryo (actually the second leaf formed) does not appear above ground until after seven to eight years, but in buds induced in decapitated shoots, four to six new leaves may be formed in five to six months Completely defoliated shoots may show a comparable rate of leaf formation. The conclusion is reached that while the fundamental pattern of development is the same in embryos and buds, the actual sequence in which the primary organs are formed, and their rate of formation and development, are referable to nutritional factors

Zoological Nomenclature

As from June 30, 1955, the International Commission on Zoological Nomenclature will start to vote on the following cases involving the possible use of the plenary powers for the purpose specified against each entry Full particulars were published on December 30, 1954, in Parts 10 and 11 of Vol 9 of the *Bulletin of Zoological Nomenclature* (1) *Dama* Frisch, 1775 (Cl Mammalia), validation of, for use for the name for the fallow deer of Europe, (2) *Helicella* Férussac, 1821 (Cl Gastropoda), validation of, (3) *rufa* Linnæus, 1761 (*Formica*), validation of, and designation as type species of *Formica* Linnæus, 1758 (Cl Insecta, Order Hymenoptera), (4) *Carnifex* Binney, 1865 (Cl Gastropoda), validation of, (5) *Discias* Rathbun, 1902, *Upogebia* Leach, 1814, *Processa* Leach, 1815, Xanthinae Dana, 1851, Upogebiinae Borradaile, 1903, and Processidae Ortmann, 1896 (Cl Crustacea, Order Decapoda), validation of Comments on these cases should be sent as soon as possible to Francis Hemming, secretary to the Commission, 28 Park Village East, Regent's Park, London, N W 1

Group Discussion

Over recent years the Central Council for Health Education (Tavistock House, Tavistock Square, London, W C 1) has published a number of articles in its quarterly journal dealing with various aspects of group discussion in educational, social and working life These evoked considerable interest and, as a result, the Council has brought them together and published them in book form They include accounts of the theory and practice of group discussion by Dr M L Johnson, preparation for a group discussion by Dr Emrys Davies, the technique of running discussion groups by M Fassam, how to run meetings by J J Gillespie and Dr J Burton, discussion in a secondary school by Frank Tyrer, the Quaker group by B Pollard, and group psychotherapy by Dr E J Anthony There is also a detailed and comprehensive bibliography

Economic Developments in Mexico

The main article in the autumn issue of *Progress*, the magazine of Unilever, Ltd, describes economic developments in Mexico It has been contributed by Dr Eduordo Villasenor, formerly director-general of the Bank of Mexico, who shows that, despite all the difficulties thrown up by the geography of the country, agrarian reform and industrialization are increasing rapidly and are being accompanied by many developments in education and welfare services Mexicans are particularly proud that their State University, which is the oldest on the American continent, now possesses the "most modern buildings and equipment of any university in the world"

Documentation in Aeronautics

At the fourth meeting of the Documentation Committee of the Advisory Group for Aeronautical Research and Development of the North Atlantic Treaty Organization in Paris during November 2–6, closer liaison was recommended between the documentation committee and the technical panels of the Group, and in particular it was suggested that the committee might assist the panels in the preparation of bibliographies Progress was reported in the preparation of the interlingual aeronautical dictionary A French version of the British Standards Institution's glossary of aeronautical terms was ready for circulation for criticism, a German translation would be ready for revision shortly, Part 1 of a Dutch translation was ready for circulation, and Part 1 of a Russian translation had been revised It was agreed to produce first individual volumes for each language, with an alphabetical index, for limited circulation in the country concerned for criticism, and not to undertake the preparation of the complete dictionary until criticisms had been received and amendments made It was also agreed to maintain contact with Dr Heflin's project for a dictionary of Air Force language

A sub-committee was appointed to review critically the production of an international abstract bulletin and, if possible, to recommend an alternative approach to the improvement of abstracting services Subject classification schemes used in aeronautics were also discussed as well as methods of retrieving punched cards, and it was recommended that, in co-operation with Unesco, a list of systems, covering the mechanics as well as methods of coding, now in use in aeronautical fields should be made Recommendations made at the previous meeting in favour of improving the availability of classified reports were confirmed and a suggestion for the preparation of a guide to the sources of aeronautical information was welcomed It was also agreed that the adequacy of the translation coverage of aeronautical literature requires close examination, and a draft report is to be prepared for the next meeting

Recent Developments in Radio Astronomy

A recent issue of "Occasional Notes of the Royal Astronomical Society" (3, No. 16; 1954) is entirely devoted to the subject of radio astronomy and is made up of ten papers by Prof. A. C. B. Lovell and his colleagues at the Jodrell Bank Experimental Station of the University of Manchester. A short introduction by Prof. Lovell is followed by two chapters dealing with radio telescopes and techniques, copiously illustrated by plates and a number of diagrams. In these the main principles underlying the use of radio telescopes are explained, and the first chapter ends with a short account of two modern instruments: the large interferometer recently brought into use in Cambridge by M. Ryle; and the pencil-beam radio telescope under construction at Jodrell Bank, which, it is hoped, will be in use in 1955. After this, the remaining eight chapters deal with the application of radio astronomy and are arranged in order of distances from the earth as follows: meteors; radio echoes from the aurora and the moon; radio waves from the sun; radio waves from the galaxy; the identification of the radio stars; the scintillation of the radio stars; radio waves from the interstellar hydrogen; radio waves of extragalactic origin. These provide adequate information for general readers interested in radio astronomy and are well illustrated (there are seven plates and twenty-seven diagrams altogether in the issue), and those who desire more extensive details will find in the bibliography a list of publications during the past eight years, several of which appeared in 1953 and 1954. Two points merit comment here. The first is that the origin of scintillations is not in the source itself but is due to varying atmospheric conditions; and, while these scintillations are very inconvenient to the radio astronomer, they provide a new technique to the geophysicist for investigating the complexities of the upper regions of the earth's atmosphere into which exploring rockets have not yet penetrated. The other is that among the normal nebulæ there may be distributed a class of nebulæ which are more powerful emitters than the normal spirals. It is difficult to say what peculiar property this class possesses, but there is support from different sources for the above suggestion, among which may be noticed the identification by Stanley and Slee of the intense sources in Virgo and Centaurus with the peculiar nebulæ NGC 4486 and NGC 5128, and the more recent identification of the intense source Cygnus 1 with two faint extra-galactic nebulæ in collision. Other lines of evidence also support the suggestion.

Exchange of Students for Technical Experience

The remarkable increase in the number of technical students who obtain practical experience in other countries during their long vacations is shown in the seventh annual report of the International Association for the Exchange of Students for Technical Experience. During 1954 the number of effective exchanges made has been 4,267 students, showing a further increase of 484 over the 1953 total. In addition, 148 students were placed between Turkey and member countries of the Association. Portugal was admitted to the Association in January 1954, and India and Turkey have made application for admission. Difficulties are being encountered in the United States in forming a central committee for the exchange of students, although many industries have signified their readiness to receive students, and the U.S. State Department has expressed willingness to facilitate the admission of students by the allocation of the necessary programme number to cover the issue of visas for visiting overseas students.

University of London: Appointments

The following appointments in the University of London have been announced: Dr. A. W. Skempton, reader in soil mechanics at the Imperial College of Science and Technology, to the University chair of soil mechanics tenable at that College; Dr. D. G. Harvey to the University readership in chemical pathology tenable at the Royal Veterinary College; Prof. Norman Millott, professor of zoology in the University College of the West Indies, to the University chair of zoology tenable at Bedford College in succession to Prof. H. Munro Fox.

Announcements

The 1955 James Watt International Medal of the Institution of Mechanical Engineers has been awarded to Dr. Igor Ivan Sikorsky, in recognition of his life's work in applying science to the progress of mechanical engineering through pioneering development of aircraft of various types—multi-engined, amphibians and particularly helicopters. The James Watt International Medal was founded to commemorate the bi-centenary of the birth of James Watt on January 19, 1736, and is the Institution's highest award.

On the occasion of the Fourth World Petroleum Congress to be held in Rome during June 6–15, an International Oil Equipment Exhibition will be organized in Naples, in the premises of the Overseas Fair (Mostra d'Oltremare). This Exhibition will remain open during June 5–20.

The group of European molecular spectroscopists, which held meetings at Basel in 1951 and Paris in 1953, has arranged to hold another meeting in Oxford during July 7–11, 1955. The subjects discussed will cover a wide range of ultra-violet, infrared and Raman work. Further information may be obtained from Dr. H. W. Thompson, St. John's College, Oxford.

A conference on "The Functions and Education of the Chemical Engineer in Europe", organized by the Institution of Chemical Engineers in co-operation with the Department of Scientific and Industrial Research for the European Productivity Agency of the Organization for European Economic Co-operation, will be held at Church House, Westminster, London, S.W.1, during March 21–23. Eleven Western European countries are expected to take part. The conference is open to official delegates and members of the Institution of Chemical Engineers. Further information can be obtained from the Institution, 56 Victoria Street, London, S.W.1.

The third annual meeting of the editorial board of the *Journal of Embryology and Experimental Morphology* will be accompanied by a conference on embryology to be held in the Palais des Académies and the Faculté de Médecine in Brussels during April 4–7. Those wishing to attend are asked to inform Prof. A. M. Dalcq, 97 rue aux Laines, Brussels, as soon as possible. (Those travelling from Britain should communicate instead with Dr. D. R. Newth, Department of Zoology, University College, London.) Requests for accommodation in Brussels must be made before February 1.

GENEVA LABORATORY OF THE BATTELLE MEMORIAL INSTITUTE

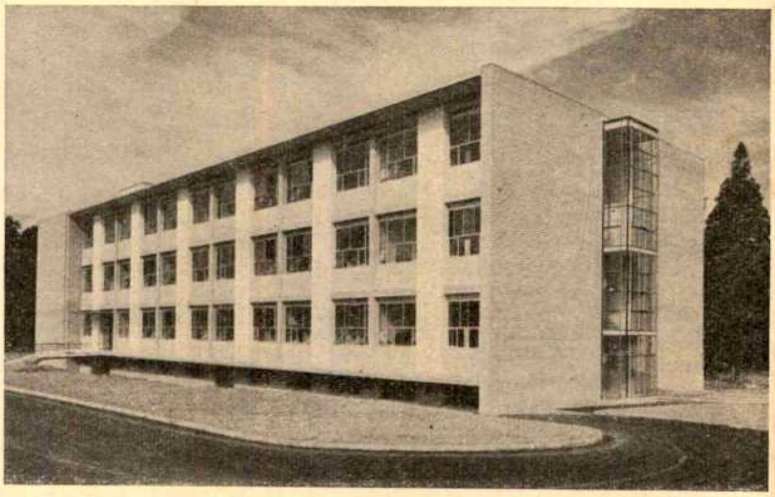
By FRANK C. CROXTON

Assistant Director in Charge of Operations in Europe, Battelle Institute

ON November 26 the Geneva Laboratory of the Battelle Memorial Institute was formally opened before an assembly of three hundred guests from five countries. M. Denis de Rougemont, author and director of the European Cultural Centre, gave an address in which he first explored the reasons for research, described by him as a spiritual passion. After reviewing the need for research, he discussed its purpose, which is the liberation of man by reducing his labours, and said that it is in the creative spirit that research institutes, especially Battelle, must work. Prof. G. Colonnetti, president of the Italian National Research Council, spoke of the benefits to be derived in future years from the peaceful applications of nuclear energy. He reminded his listeners that machines have not caused unemployment but that, on the other hand, man is not yet master of the machine to the extent that he is called on for his intelligence rather than his muscles. He doubted the value of research if the results are applied without concern for their effect on society. Prof. L. Jacqué, professor of chemistry in the École Polytechnique, Paris, described the participation of French scientific workers in the important technical developments of the world and continued by reviewing some of the notable chemical discoveries of recent times. He spoke of several of the research institutions working for the advancement of science and technology and referred especially to organizations such as Battelle and the services that they can render.

The Battelle Laboratory at Geneva is one of three which, with a marine research station in Florida, constitute the Institute's experimental facilities. In addition to its main offices at the Columbus Laboratory and also laboratories at Frankfurt am Main, it also has offices in London, Madrid, Milan and Paris. The Battelle Institute was founded by the bequest of Gordon Battelle, and research was begun in 1929, so that 1954 marks its silver jubilee year. Its intention during this time has been to provide research services of a very practical sort, designed to fit the needs of industry. Although its beginnings were in metallurgy and fuels, the Institute was requested to enter many allied fields, until now it can be said to carry out research and development programmes in essentially all fields of technology. The Institute was originally pictured as of local significance; but as it grew it was soon serving industries from all parts of the United States as well as those of several other countries. It became apparent that Battelle's research services should be made available more generally, and so laboratories were constructed at [redacted]kfurt and now at Geneva. It is doubtful whether Gordon Battelle envisaged the expansion of the contract-research concept to an international scope; but his original ideas of providing research services to industry and thus to mankind have been fully implemented by this step.

The perfectly rectangular building of the new Geneva Laboratory consists of three stories and basement and is situated on a 22-acre plot of land in Carouge, a suburb of Geneva; with it are a villa and a farm building. Immediately after its reconstruction, it was necessary to use the villa for housing the essential requirements; but now it is used for the administrative offices, library and the telephone exchange. The farm building contains the machine shop, carpentry shop and garage. At the earliest possible moment the laboratory building was begun. It was completed only a few weeks before the official opening, but was quickly occupied by the technical staff and their apparatus. This building has a floor area of forty thousand square feet. At one end, the pilot-plant laboratory extends from the ground-floor level to the roof, a height of about thirty-two feet, which permits the installation of tall distillation or extraction columns. The auxiliary apparatus can be placed on the ground floor and on balconies at each of the higher floor-levels. The general laboratories are built on a modular basis. Partitions between them are of non-load-bearing construction to permit removal when necessary for alterations. Hot and cold water, gas and air are available for each unit, as are ducts for hoods where necessary. Both the Geneva and Frankfurt Laboratories use the bus-bar duct system of power distribution which provides the flexibility so frequently needed in a research building. The painted concrete floors are economical but clean, and lighting is at a high level to increase efficiency and accuracy. The stairways are constructed in a rather novel manner permitting each flight to be lifted aside, thus leaving a completely open stairwell for the hoisting of heavy equipment; in addition, there is a combination freight and passenger lift.



Battelle Laboratory at Carouge–Geneva

The Battelle Institute undertakes research for the sole benefit of each client and hands over all results, including patents, the work being carried out on a completely confidential basis. At Geneva, research is being done in physics, chemistry and metallurgy by the staff of eighty-five people. Serious consideration is given to new fields of research as industry demands them, so that, like the Columbus and Frankfurt Laboratories, the Geneva Laboratory is a dynamic rather than a static organization. Each project receives the full attention of the Institute's entire research facilities in the United States and Europe. The volume of research already achieved makes it evident that the Battelle Institute can be as helpful in Europe as it has been in the country of its origin.

THE COLOMBO PLAN: TECHNICAL CO-OPERATION SCHEME

UNDER the Technical Co-operation Scheme of the Colombo Plan, which completed its fourth year in June 1954 (The Colombo Plan. Technical Co-operation Scheme. Report for 1953–54 by the Council for Technical Co-operation in South and South-East Asia. Colombo, July 1954. London: H.M.S.O., 1954. 1*s* net), training was arranged in 1953 for 608 persons as against 538 in 1952, and 1,653 places have now been provided in all, mostly for graduates with a background of experience which enables them to benefit from their specialist training abroad in various fields of economic development. By June 30, 1954, the largest group (268) went abroad for training in food and agriculture; of the others, training in government administration claimed 266, engineering 192, medicine and health 168, education 135, transport and communications 132, industry and trade 131, and power and fuel 123. The United Kingdom provided facilities for 638 trainees, including 211 from India, 195 from Ceylon and 157 from Pakistan. Of Australia's 487 trainees, 116 came from India, 91 from Pakistan, 80 from Indonesia and 79 from Ceylon. Canada has taken 210 trainees (93 from Pakistan and 92 from India), New Zealand, 170 (45 from Ceylon, 39 from Malaya, 35 from India and 32 from Pakistan), while India has taken 137 trainees, including 67 from Ceylon and 23 from Pakistan. The figures indicate that while Pakistan and Indonesia are concentrating on training in administration, India and Ceylon are concentrating on training facilities in food and agriculture.

The demand for experts has been heaviest in the field of medicine and health. The 58 experts provided in 1953 (compared with 90 in 1952 and 45 in 1951) brought the total provided to 263 as against 502 applied for; and of these, 69 are in medicine and health, 36 in transport and communication, 33 in engineering, 33 in food, agriculture and forestry, 25 in education and 23 in industry and trade. Of the 115 experts provided by the United Kingdom, both India and Ceylon took fifty. Of 45 supplied by Canada, 22 went to Ceylon, 10 to Pakistan and 9 to Malaya. Of New Zealand's 30 experts, 12 went to Pakistan. Although 239 requests were outstanding, offers are still awaited against only 133.

Requests for equipment for use by experts or for training and research institutions since the beginning of the Scheme have totalled £1·5 million, against which equipment to the value of £1 million has been supplied or offered. Requests totalling £714,500 have been received from Pakistan, £591,700 from India and £171,000 from Ceylon. Equipment supplied or agreed in principle by the United Kingdom includes £14,000 worth for the Technical High School, Karachi, and £155,000 for nine new technical high-schools in Pakistan, £50,000 worth for the Mercantile Marine Academy, Pakistan, and £82,000 for the Pakistan Department of Scientific and Industrial Research, £139,000 for the Textile Training Centre, Lyallpur, £70,000 for the National Metallurgical Laboratory, Jamshedpur, £24,000 for the Central Testing and Standards Laboratories at Karachi and Dacca, £37,500 for the Central Water Power, Irrigation and Navigation Research Station, Poona, £12,380 for the Bengal Engineering College, Calcutta, £18,300 for the Research Laboratory of the Forest and Education Branch of the Ceylon Forest Department, £25,000 for the Central Science Teaching Centre, Bandung, and Teacher Training Centres at Djogjakarta and Surabaya.

BIOLOGY AND A GENERAL UNIVERSITY EDUCATION

A CONFERENCE on "Biology and a General University Education", organized by the Institute of Biology, was held at the University College of North Staffordshire, Keele, on December 20–21. Most of those attending were paying their first visit to Keele, and it was clear from what was said at dinner-table and in common rooms that they generally liked what they saw and heard of the College. There was appreciation, too, of the inclusion in the general education for which North Staffordshire stands, not only of biology but also of those traditional academic graces which are so conspicuously lacking in some of the universities born of the industrial revolution.

In the first session, under the chairmanship of Prof. S. Zuckerman, three speakers described biology courses for arts students that are already in existence. Prof. A. R. Gemmell dealt with biology as one alternative for the compulsory natural science subject for students of the humanities or social sciences at Keele. He tries to give his students an insight into the scientist's approach and some knowledge of the nature of laboratory work, to relate the science to the student's own background of knowledge, and to stimulate him to think. The centre of the course is man, and there are fifty-two lectures, on mammalian physiology and anatomy, parasitism and disease, genetics and agriculture. There is a three-hour practical class each week, including dissection of the rabbit and some work with *Drosophila*. Dr. J. Hutchens (Chicago) then described biology as a part of the general education course at his university. Here physical science is studied as well, and before biology, and the students include those who will later specialize in sciences as well as the humanities. The emphasis in the biology course is on the physiology of man; but the laboratory course begins with microscopy—pond water, blood cells and so on—a practice of which Dr. Hutchens does not ap[illegible]. There are differences of approach in different parts of the course, some stressing details and others general principles. For the most part, the teaching in general education is done by a separate staff from that of the divisions which deal with higher degrees; this frees research workers whose chief interest is the multiplication of published papers from work which will not lead to their academic advancement, but has the unfortunate effect of making the others, whose job is teaching rather than research, feel somewhat second-class.

Dr C Gordon dealt with a course in social biology which he gives to social science students at Edinburgh; this is complementary to one in anatomy and physiology given by a physician. The biology is academic and vocational and includes topics such as man's place in the animal kingdom, the effects of heredity and environment, and some discussion of physiology and vital statistics. The students take an examination at the end of the course, and their answers are on the whole well written but show no evidence of any ability to interpret data. This is partly because the students are frightened of mathematics, but may also be due to the absence of any practical work, which the scientists have not yet been able to induce the board of studies to impose.

In the subsequent discussion, a number of speakers said that they could give a better education if they had students for four years instead of three; but there was no general agreement on the meaning of a fourth year or on what to do with it. For some, it seemed to mean ignoring what the students had done at school or teaching them again what they had already had the opportunity of learning there; for others it meant the possibility of lengthening and strengthening the course for an honours degree. The sense of the meeting was probably that it is a good thing to have a specialist staff to teach science to arts students; but that its members should also take part in straightforward research, and that some form of practical work is desirable.

In the afternoon Prof Gemmell took the chair, and the conference heard three professors at North Staffordshire say how useful his biology course was for their students. Prof. S Finer (social science) found its advantage to be that it taught them the background of knowledge of human ecology necessary for their practical work; Prof. W C. Stewart (education) welcomed it for its aid in the understanding of child development; and Prof J. Blake (history) liked its broadening of outlook and its development of a different aspect of truth from those with which the historian and philosopher deal. In the absence through illness of Mr. L J F Brimble, Mr W B. Yapp (Birmingham) gave the only other set paper in this session, which had the title "Biology for Arts Students—Is it worthwhile ?" He suggested that in order for such courses to be justified, there had to be a successful solution of the problem of language, careful selection of topics which are wide in scope but deep in the demands which they make on the students' understanding, and even more careful selection of the teacher. Referring to the theory of organic evolution as probably the best single topic, both on theoretical grounds and in practice, he said that those who taught it to arts students should have a wide background of knowledge and in particular ought to have read "The Origin of Species". This divided the audience, or at least the vocal part of it, fairly evenly into those who had read the book and agreed with the speaker, and those who had not and thought it unnecessary to do so. In the rest of the discussion Prof T. A Bennet-Clark (King's College, London) voiced the disappointment of many of the biologists when he said that the three Keele speakers had all spoken chiefly of the value of biology on vocational grounds.

The final session, with Prof O. E Lowenstein in the chair, was on "Biology in a General Science Education". Prof Bennet-Clark defended it as suitable for third-class and pass-degree men who would enter commerce, and felt that a training in science gives a better education, in A N Whitehead's sense of "a habitual vision of greatness", than is now possible for the humanities. Prof F W R. Brambell (Bangor) put the case against general science by arguing for the virtues of specialization on educational grounds. He recommended opportunism in the choice of advanced courses, and the pursuit of them to the forefront of knowledge according to the interests of the staff available. Among points raised in the general discussion were the difficulty that early study of the basic sciences often lays down special interests at school (Dr Gordon), the need for courses not leading to a professional career in biology (Dr. Hutchens), the advantage of an encyclopædic knowledge (Prof Lowenstein), the importance of knowing when one is ignorant (Mrs Riddiford), and the value of a biological training in teaching one to deal with complex situations. There seemed in the end to be a greater measure of agreement between the two principal speakers than at first appeared. Both wanted as much specialization as possible for those who could profit from it, and both held that biology had more to offer than its mere vocational value for those who would use it in after life. One of the most pleasing aspects of the conference was the general feeling that a university training in biology can be one of the best preparations for entry to those careers in administration and leadership for which we have not yet designed precise undergraduate courses. Biology, in fact, might well take part of the place so long occupied by the classics but for which they are no longer fitted. One would like to see a full and reasoned statement of this view, which was implicit rather than openly said in much that passed at the conference.

W. B. YAPP

GASEOUS ELECTRONICS

CONFERENCE IN NEW YORK

THE Gaseous Electronics Conference has now become an annual meeting in the United States which is greatly looked forward to by all those interested in the subject. The 1954 Conference was sponsored by the Division of Electron Physics of the American Physical Society, and the host institution was the College of Engineering of New York University, which is celebrating its centenary. The meetings were held in New York City during October 14–16, and were attended by about 240 members from all over the United States and Canada. More than a third of the forty-five papers (forty-one contributed and four invited) came from universities, the rest coming from the great industrial laboratories and government establishments, representing in all twenty-seven different organizations. Members of the Conference were entertained at a banquet at which the guest speakers were Dr. T E. Allibone, of Associated Electrical Industries, Aldermaston, who described current work in England on gaseous electronics, and Dr W. Finkelnburg, of Siemens-Schuckert, Erlangen, who described present-day

German work in this field. The chairman of the Committee of the Conference was Dr. W. P. Allis, of the Massachusetts Institute of Technology, and Dr. L. H. Fisher, of New York University, as secretary, was responsible for the excellent Conference arrangements.

A very wide field was covered in the papers and it is not possible in this brief report to describe the material in any detail: their subject-matters ranged from atomic cross-sections to the properties of complicated statistical assemblies such as the high-temperature arc. Of late years much work has been done in improving modern vacuum techniques and in the preparation of pure gases and of clean surfaces, and this has led to the re-evaluation of some fundamental ionization and collision data. Among such papers were those of W. H. Hickman and R. E. Fox (Westinghouse) on negative-ion formation using low (0·1-eV.) mono-energetic electrons, the narrow capture process yielding information about the behaviour of such electron beams, and that of E. Gerjuoy (Pittsburg) and S. Stein (Westinghouse) discussing theoretical work on rotational excitations by slow electrons. L. M. Branscomb (Bureau of Standards) described measurements of the photo-detachment cross-section for the hydrogen atom, obtaining a result within 10 per cent of that calculated by Chandrasekhar. N. Wainfan, W. C. Walker and G. L. Weissler (Southern California) reported determinations of cross-sections for photo-ionization of carbon dioxide, argon and the hydrogen and water molecules in the wave-length range 473–1100 A., and of photoelectric yields in the vacuum ultra-violet. The atomic absorption cross-section of atomic nitrogen found by A. W. Ehler and G. L. Weissler agrees with that calculated by Bates. D. J. Rose (Bell Laboratories) reported recent determinations of Townsend's α in hydrogen over the range $20 < Z/p < 1{,}000$ V./cm. mm. mercury, assessing disagreements between previous determinations. H. D. Hagstrum (Bell Laboratories) described determinations of the secondary emission of electrons from surfaces either atomically clean or contaminated by a monomolecular gas layer. With clean surfaces $\gamma_{\max}$ for He$^+$ is found to be $\sim 0{\cdot}2$ and largely independent of ion energy; but for contaminated surfaces γ increases with ion energy and may become as high as unity. F. Keywell (Bell Laboratories) discussed high-vacuum sputtering. R. N. Varney (Washington) reported work on diffusion, and A. V. Phelps (Westinghouse) described the diffusion and volume-loss coefficients of helium metastable atoms and molecules; and the life-time of metastable mercury molecules was discussed by C. G. Matland and A. O. McCoubrey (Westinghouse).

Another group of papers dealt with the physics of plasma. Plasma oscillations were considered by J. E. Drummond and L. Wilcox (Sylvania); fluctuations in crossed electric and magnetic fields by H. W. Batten (Michigan); travelling striations by N. L. Oleson (U.S. Naval Postgraduate School); noise mechanism by M. I. Skolnik (Johns Hopkins); aspects of plasma resonance by K. S. W. Champion and S. C. Brown, and a microwave study of positive ion collection using probes by G. J. Schulz and S. C. Brown (Massachusetts Institute of Technology); cumulative ionization processes in the helium positive column by L. S. Frost and A. V. Phelps (Westinghouse).

A number of papers dealt with properties of the electric arc. Low-voltage phenomena were discussed by E. O. Johnson (R.C.A.) and extreme temperature phenomena by W. Finkelnburg (Siemens-Schukert). Other aspects of discharge phenomena were described in a session which included an invited paper by H. Margenau (Yale) on the effect of electrons on spectral lines emitted in a discharge, and papers on the cathode spot arc by Robert St. John, J. G. Winans (Wisconsin) and by C. G. Smith (Raytheon). D.C. arcs in a magnetic field were discussed by L. P. Winsor (Rensslaer) and T. H. Lee (General Electric), and R. W. Warren (California) reported measurements of electric fields in glow discharges.

A third of the programme was devoted to papers on electrical breakdown, and, in particular, to the ionization processes by which the ionization builds up on the application of electric fields.

Variation of mean free paths in discharges was considered by I. A. MacLennan and A. D. MacDonald (Dalhousie). Two papers on the influence of field emission on Paschen's law at high pressure and in vacuum phenomena breakdown were given by L. H. Germer, P. Kisliuk and W. S. Boyle (Bell Laboratories). The influence of molecular structure on the sparking potential of hydrocarbon gases was discussed by R. W. Crowe and J. C. Devins (General Electric). A paper by E. L. Huber (California) described work on corona breakdown in nitrogen and oxygen and mixtures, using α-particle triggering. Further experimental evidence on the development of a Townsend avalanche preceding breakdown was given by H. W. Bandel (California) for air, and for argon by M. Menes (Westinghouse), who suggested a process involving delayed photon emission. A session was devoted to a symposium of three invited papers on breakdown. A paper on the mechanism of uniform field static breakdown was given by F. Llewellyn Jones (Swansea, Wales), a paper on the formative time-lags of uniform field breakdown by L. H. Fisher (New York), and a paper on secondary processes and the mechanisms of spark breakdown by L. B. Loeb (California). The ensuing discussion indicated a general agreement on the role taken by the electron avalanche and the secondary ionization processes, and, while helping to clarify terminology, also indicated the field that still awaits complete quantitative explanation—as that of the complete build-up to a high current-density spark-channel after the applied voltage had attained or exceeded the static breakdown potential.

Miscellaneous subjects were dealt with in papers by C. Kenty (General Electric) on metallic flames excited by active nitrogen, by H. P. Broida (National Bureau of Standards) on afterglow of solid nitrogen, and by W. M. Brubaker (Consolidated Engineering Corp.) on space charges in mass-spectrometer ion sources. Probes for space-charge fields were discussed by P. Coopermann (Research Corporation), electronic tuning of microwave cavities by F. R. Arams and H. K. Jenny (R.C.A.), ionization in long nitrogen afterglows by W. B. Kunkel and A. L. Gardner (California), and studies of anode pre-breakdown phenomena in thyratrons were described by S. Goldberg (Edgerton, Germeshausen and Grier, Inc.). Fire-ball discharges were discussed by G. Medicus (Wright Air Development Center) and by K. G. Henquist and E. O. Johnson (R.C.A.).

In closing the Conference, Dr. W. P. Allis mentioned that the general subject for the conference to be held next year will be discharge phenomena at extremely high temperatures.

F. Llewellyn Jones

PRODUCTION OF TOWN GAS BY GASIFICATION PROCESSES

ON September 3 at the recent British Association meeting in Oxford, Dr F J Dent, director of the Gas Council's Birmingham Research Station, read a paper to Section B (Chemistry) on the gasification of coal He began by pointing out that town gas has most of the properties of an ideal fuel, being smokeless, clean, convenient and amenable to precise control Its use has increased steadily, until now the heat units distributed as gas are equal to 6 per cent of those in the total coal mined, with an estimated annual saving of more than twenty million tons of coal At a time when it has never been more important to economize in coal, when everyone is acutely conscious of the evils of air pollution, and when the refinement of industrial processes needs corresponding refinement in methods of heating, it is of prime importance to know whether much more coal could not be gasified so that the use of gas could be extended to general heating purposes On the grounds of cost alone, this would require the coal to be converted at high thermal efficiency in a relatively cheap plant, and clearly there must be little restriction as regards the type of coal There must also be flexibility in operation, since the more extensive is the use of gas, the more desirable will it be to suit production to variations in demand

In the light of recent technical advances it seems that all these requirements will soon be attainable, but only by having some alternative to carbonization, the principal process now used for gas manufacture The carbonization of coal, operated since gas was first introduced for lighting, is now highly developed, but it has limitations which would probably militate seriously against a further major increase in gas production To some extent these are due to the cost and inflexibility of the plant, but, more particularly, they are concerned with coal supplies which, for carbonization, must be of a special kind, rich in volatile matter to give sufficient gas, reasonably low in ash, and fusible enough to produce a good coke But, while all coal is scarce, it is this caking type which is becoming the most difficult to obtain The plans of the Coal Board are to mine a greater proportion of weakly caking coal, and more mechanization is expected to increase the production of high-ash smalls. These are likely to be the coals most readily available for gas manufacture and, except in limited quantities, they are unsuitable for carbonization It is for these reasons that a large increase in the production of gas from coal seems to require some other process We now believe that one with the desired features will soon be obtainable, and it will gasify the coal completely as a result of the initial thermal decomposition being followed by the reaction of residual carbon with steam,

$$C + H_2O \rightarrow CO + H_2$$

It is as well, however, to appreciate what such a process involves since, clearly, its chemistry is quite different from that of carbonization A gasification system absorbs the elements of water and does not reject carbon as coke; but yet, for a time at least, the gas finally obtained must be interchangeable with that from existing plants. The gas need not have the same empirical composition as coal gas, but for satisfactory behaviour in appliances, it must be of similar calorific value and density It must have calorific value of 450–500 B Th U per cu. ft and density of about 0 5 (air = 1).

The composition of coal is then sufficient to show that, in meeting this requirement, besides providing for the straightforward reaction with steam, a suitable gasification process must (a) increase th production of methane above that normally obtaine by thermal decomposition so as to give the require calorific value in the greater volume of gas obtaine per ton of coal, and (b) avoid too high a density in the gas by rejecting both carbon and oxygen This can be done by converting carbon monoxide t hydrogen by means of additional steam and then removing carbon dioxide,

$$CO + H_2O \rightarrow H_2 + CO_2$$

Until a few years before the Second World War these operations always appeared formidable Indeed it can be argued that it has been because of their that carbonization has persisted as the basic method of gas manufacture In 1935, however, the Lurg process was introduced in Germany and showed that a considerable simplification could be obtained by conducting the whole of the gasification under a pressure of several atmospheres The Lurgi process uses a generator, similar in design to a norma mechanical producer, except that it allows gasification to be carried out in steam at 20–30 atmospheres Oxygen is added to the steam to liberate the heat required by the gasification reaction, and the output is readily variable through the rate at which this oxygen and steam mixture is supplied. The unique feature is, however, the use of pressure, which is found to have several advantages it reduces gas velocities through the fuel bed so that small fuel can be gasified at high output with little loss of dust from the generator, under pressure, methane is stable at the temperature of the fuel bed and is formed during the gasification itself, steam, used in excess to prevent clinker formation, reacts in the fuel-bed with carbon monoxide, and the density of the final gas is quite normal; pressure then facilitates the removal of the carbon dioxide by washing the gas with water or, preferably, with organic solvents, which also eliminate gum formers and sulphur compounds, to give a higher standard of purity than has hitherto been attained in town gas

This process was initially developed for the gasification of lignite. Large installations have been operated on the Continent of Europe, and more are being erected It clearly has most of the desired features In fact, technically, only two further developments are required before its use in Great Britain, and these are, first, a modification of the generator so that it would gasify bituminous coals, which differ from lignite in that they tend to agglomerate when heated under pressure and, secondly, an increase in the calorific value of the gas which, at 400–450 B Th.U per cu ft, is still rather low.

Modifications to the design of the generator have been made in Germany, and tests have shown that it is now capable of dealing with a wide range of British weakly-caking coals The increase in calorific value has also been achieved, work in Britain having concentrated on this aspect It has been found that the formation of additional methane under pressure is the result of hydrogen from steam reacting with the coal and that the extent of this hydrogenation eaction can be increased if the best use is made of he pressure available

The process can therefore be regarded as satisfactory in so far as it will produce a suitable gas from ow-grade coals, and the capital charges are only about half those of carbonization. Are its overall economics also satisfactory? So far as can be ascertained without full-scale trial in Britain, the cost of gas production would, in many localities, be ower than by carbonization but not low enough for he expansion of gas production as contemplated by Dr Dent In its present form, therefore, the Lurgi process is mainly to be regarded as a method for widening the range of the coals used for gas-making, and it is important on that account Is there, however, opportunity for the further development of what is still a relatively new process? Dr Dent hinks that there is

Because of the nature of the process, development will not be confined to any single feature As already indicated, the conversion of coal to gas involves a number of steps, and minimum costs will only be achieved if each is carried out at maximum efficiency If gas is to be competitive for general heating, production processes must leave no margin of avoidable losses and take full advantage of there being no estriction by natural laws such as those which limit the efficiency of utilizing coal for power generation Then it is realized that, while a first attraction of the Lurgi process is that the gasification in steam, the conversion of carbon monoxide, and the formation of methane occur in the one fuel bed, the individual performances do not compare favourably with those attained under other conditions, and they are all capable of improvement

Consideration indicates that maximum performances will only be obtained by having separate control at each stage, and this is quite logical Efficient reaction with steam requires a high temperature, efficient conversion of carbon monoxide a low one, while the production of methane is favoured by an intermediate range with the partial pressure of hydrogen as high as possible Optimum conditions for each cannot be obtained in the same fuel-bed, and all experimental work indicates that individual control will improve both efficiency and flexibility In more detail, developments being considered are ncreasing steam decomposition by operating with higher temperatures in the fuel bed, and withdrawing the ash as a slag—the thermal efficiency of gasification will then approach 80 per cent, obtaining the maximum efficiency in carbon monoxide conversion by using catalysts in a separate stage incorporating the removal of carbon dioxide, and enriching the gas by means of the hydrogenation reaction, and again in a separate stage and after steam, carbon monoxide and carbon dioxide have been removed o that the pressure of the remaining hydrogen is as high as possible

The plant lay-out will then consist of boiler plant, oxygen plant, gasification stage, condensation with rejection of tar and liquor, removal of hydrogen sulphide, conversion of carbon monoxide and removal of carbon dioxide, enrichment stage, and final purification

This system underlies a programme of research being carried out in Britain by the Gas Council It will be appreciated that it is more comprehensive than the present Lurgi process and represents rather the full development of pressure gasification for the production of town gas Thus, while the gasification stage may have standard or slagging generators, it may also include units for the fluidized or suspended gasification of powdered coal, breeze, tar and petroleum oils, as well as for the reforming of natural and other fuel gases, and similarly in the enrichment stage In fact, once a works has been laid out for pressure gasification with oxygen, steam supplies, etc, it would be relatively simple to effect modifications in the gasification and enrichment stages to suit any raw material. Further, whatever raw material were used, the composition of the final gas could correspond with any calorific value up to 1,000 B.Th.U per cu. ft, a fundamental feature characteristic of pressure operation, as reactions can be governed by equilibria at every stage, this is different, for example, from a process of thermal decomposition such as carbonization, in which so much depends upon the nature of the coal As in Lurgi gas, there would be only four simple gas constituents—namely, carbon monoxide, hydrogen, methane and nitrogen—but now, with the proportions of each constituent under full control, the methane determines the calorific value, the ratio of hydrogen to carbon monoxide determines the output, and the nitrogen controls the gas density Eventually, there might be no restriction to the present properties of coal gas, and then gas composition could be chosen to suit distribution and use

When it is coal that is being hydrogenated in the enriching stage of the system outlined above, the solid residue might be transferred to the gasification stage for the production of hydrogen-rich gas It should be noticed, however, that during hydrogenation, most of the sulphur in the coal is removed and recovered as hydrogen sulphide, and the residue contains only 0 1–0 2 per cent of this constituent Being also readily combustible, the residue might therefore find other applications, for example, as basis of a solid smokeless domestic fuel or as a fuel for power stations, when the flue gases would no longer call for treatment

The significance of pressure gasification is due to its adaptability in so many directions which embrace most, if not all, of the production features that have been sought at various times With this unique characteristic, it goes far beyond the immediate requirement for an alternative to carbonization, and offers a unified system of gas-making capable of suiting any foreseeable circumstances If the gas industry is to become the purveyor of refined heat for general purposes—a greater part than it has played in the past—then it needs some such system to facilitate the assumption of its wider function, opportunity for which has been increased by the broader groupings set up in Britain by nationalization. Particular mention might be made of the high rates of gasification obtained under pressure, which allow high outputs from individual gas-making units without an increase of the labour force, while, more obviously, the distribution of gas over longer distances at the high pressures would allow manufacture to be concentrated in large works, sited with respect to supplies and raw materials, whatever they might be Finally, the overall cost of gas production on the basis of heat units should be little more than twice the cost of pithead coal Taking into account its greater efficiency in use, its high purity and its convenience this should make gas competitive with solid fuel for a wide range of heating purposes, and it is therefore believed that gas will satisfy a far greater proportion of the demand for smokeless fuel than is generally contemplated Then, with production of an overall thermal efficiency of approximately 80 per cent, there will be a considerable saving in coal

The technical developments which have been envisaged are not regarded as aims for the distant future Vigorous investigations of gasification processes are being carried out in various parts of the world, and much is now known of the use of oxygen, slagging operation, powder techniques, hydrogenation, oil gasification and so on What remains to be done consists mainly of selecting those elements which lead to the highest performance and integrating them into the pressure system Without minimizing the effort required for this final stage, it is nevertheless believed that, with the Lurgi process as a basis on which to build, a flexible system of gas production could be made available in a few years

MEDICAL RESEARCH COUNCIL

REPORT FOR THE YEAR 1952–53

A FEATURE of the report for 1952–53 of the Medical Research Council* is an article entitled "Medical Research in the Tropics", which discusses the origin and work of the Colonial Medical Research Committee set up eight years ago by the Secretary of State for the Colonies and the Medical Research Council, under the chairmanship of the Secretary of the Medical Research Council During the eight years since the establishment of this Committee, new centres of research have been built at Fajara in the Gambia, Mwanza in Tanganyika, Oshodi in Nigeria, Kumba in the Cameroons, and Kerugoya in Kenya, and the Rockefeller Foundation generously transferred to the Colonial Office its virus research institutes at Entebbe in Uganda and Yaba in Nigeria Research laboratories were built at Makerere College in Uganda, and support was given to research in Malaya and to work on malaria in Tanganyika The Committee also advised that a Colonial Medical Service should be created, and, although this was instituted in 1949, recruits to it have been slow in coming forward

Recently, however, the control of this Colonial research has been reorganized It is not easy to disentangle from the paragraph describing this reorganization exactly what has been done, but the new arrangements provide "for decentralising to inter-territorial bodies the immediate scientific supervision of research schemes based in the colonies" and a "home-based organisation will continue to centre on the Colonial Medical Research Committee, whose terms of reference have been revised to accord with the newer concept of its duties" One is tempted to wonder, as one reads and tries to understand exactly how this complex organization works, which seems to the authorities to be the more important—the administrative machine or the men and women, at home and abroad, on whose devoted and unpublicized labours the whole organization, and also the health of a great many people, depend

The rest of the Council's report follows the plan adopted during the past few years It does not attempt to record the results of the work of the Council's separate research establishments, but gives only brief summaries, in the form of headings, of the work of each department For further information the reader is referred to the bibliography of papers published by individual research workers. The practice now is to discuss, under the title "Some Aspects of Medical Research", selected general trend of medical research "often from a broader standpoint than that of the contributions made by work within the Council's own programme", a practice which "inevitably omits mention of many investigations in which the Council's workers take part"

Following this practice, the present report discusses in the section on "Some Aspects of Medical Research" high-altitude research and the Everest expedition, cell metabolism, peripheral nerve injuries, the diagnosis and treatment of virus diseases, the grafting of tissues, the biosynthesis and metabolism of some simple nitrogenous compounds, high blood pressure, the use of cortisone and adrenocorticotropic hormone in rheumatic diseases, studies of twins, hazards in the use of pesticides, the use of hypothermia in surgery, and lipid metabolism The section is a valuable one, but some readers, however much they welcome contributions of this kind, will regret that it is no longer possible to have reports of the work being done by individual workers G LAPAGE

FORESTRY IN THE GOLD COAST

REPORT FOR THE YEAR 1952–53

THE report for the year 1952–53 of the Forest Department of the Gold Coast* gives evidence that under the new governmental régime in the Gold Coast the forests and their well-being are not to be neglected Twenty years ago the gazetted forest staff numbered twelve officers, mostly stationed in the south, the northern territories scarcely coming into forestry consideration by the forestry authorities At present, so the Chief Conservator of Forests states, the sanctioned Colonial Forest Service is thirty-five officers In addition, the sanctioned subordinate staff consists of twenty-four senior forest rangers and a hundred and twenty forest rangers with the necessary complement of forest guards Such a trained staff will, it may be hoped, be continued under the new government

The report shows most satisfactory progress The formation of a working plans branch, concerned with the enunciation of the approved forest policy, points to this In the report for 1948–49 (see *Nature*, 167, 598, 1951) it was stated that a new and detailed forest policy formulated in 1946 had been formally approved by the Governor in Council and that one of the chief aims was the management of permanent forest resources by methods that would achieve maximum productivity on the basis of a sustained yield This is a familiar aspiration, often repeated in the past in forestry reports, but the Department is making considerable progress towards its fulfilment The policy is briefly summed up under one heading—reservation—most of which has reached completion except in the Northern Territories Management over 4,583 square miles of forest reserves has now been covered by enumeration surveys, mainly on a one per cent basis of sampling, and a working plans branch was set up during the year, the total area of reserves under working plans being 880 square miles

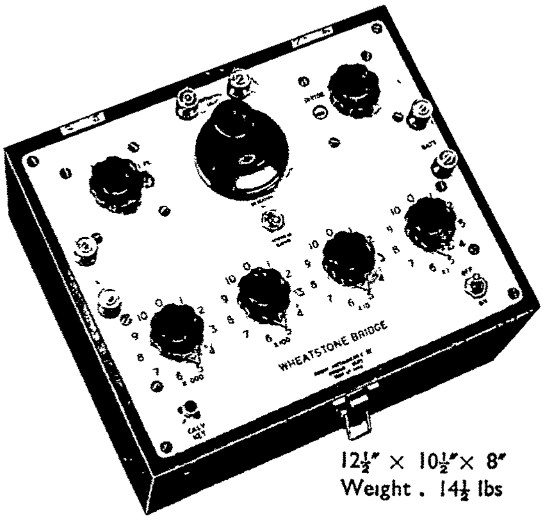
DORAN

Self-contained Wheatstone Bridge

Cat. No. E.3378



12½″ × 10½″× 8″
Weight . 14½ lbs

The instrument illustrated comprises four decade resistance units totalling 11,110 ohms with ratio arms to cover a range of measurement of from 0·01 ohm to 10 megohms. The galvanometer provided has ample sensitivity for the greater part of the range, but terminals with change-over switch enable an external galvanometer to be employed for more precise work.

Further details of this and a precision type bridge will be found in List 108 N.

Two minutes from Tottenham Court Road Station

THE PHYSICAL SOCIETY'S 39th EXHIBITION
of
SCIENTIFIC INSTRUMENTS AND APPARATUS

will be held at the
ROYAL HORTICULTURAL SOCIETY'S
NEW HALL
Greycoat and Elverton Streets, Westminster,
S W 1
from 25th–28th April, 1955

The *Handbook*, which will be published in connection with the Exhibition, is not only a catalogue, but is a most valuable reference book of new developments in British scientific instruments and apparatus

During the Exhibition, discourses on scientific subjects of general interest will be given

The Annual Craftsmanship and Draughtsmanship Competition takes place early in the year, and the winning entries will be exhibited

London, S W 7

Important Teaching Aid

PHYSICOCHEMICAL CALCULATIONS

By **E. A. GUGGENHEIM,** *Professor of Chemistry,* and **J. E. PRUE,** *Lecturer in Chemistry, University of Reading, Reading, England*

This book is the outgrowth of the long educational experience of one of the leading modern experts in thermodynamics, Professor E A Guggenheim, and of his collaborator 172 problems of physical chemistry are presented in a most original manner Each problem is divided into four sections, namely

1 Data, including detailed references to the sources
2 Introduction, where the procedure for the calculation is described
3 Calculation, including full numerical details with particular attention to units, whenever graphs have been used, small-scale reproductions of these are given
4 Discussion, in which the significance of the results and their relation to other work is assessed

This book, therefore, teaches students how to master the evaluation of their own experimental findings and how to derive numerical results from an interpretation of the original literature In selecting and grouping the problems, the authors have tried to make clear how different experimental methods can be applied for the establishment of a particular physical constant and how the results of these different methods compare with each other in reliability and accuracy For example, they present ten methods for the establishment of Avogadro's number

The book is destined to become an indispensable aid in every course in physical chemistry and chemical physics

CONTENTS

Atomic and Molecular Weights
Avogadro's Number
Molecular Velocities
Interatomic Distances
Moments of Inertia
Characteristic Frequencies
Electric Moments and Polarizabilities
Energies and Enthalpies
Entropies
Heat Capacities
Equation of State
Mixtures of Non-Electrolytes
Electrolyte Solutions
Conductances and Diffusion of Electrolytes
Gaseous Equilibria
Solution Equilibria
Acid-Base Equilibria
General Electrolyte Equilibria
Solid Surfaces
Liquid Surfaces
Gas Kinetics
Solution Kinetics
Radioactivity

Advanced Level Examples in Physics

R. V. JOHNS, M.A., B.Sc.

Lecturer in Physics and Mathematics, City of Liverpool College of Technology

W. F. WARE, B.Sc., A.Inst.P.

Senior Physics Master, Cathays High School for Boys, Cardiff

This book of numerical examples is designed to supplement the theoretical and laboratory work of students preparing for examinations in Physics at the Advanced level of the General Certificate of Education and for Intermediate Degree examinations. Some 1,000 examples have been arranged by topics and carefully graded in difficulty. Contents are arranged under the headings Mechanics and Properties of Matter, Heat, Light, Sound, and Magnetism and Electricity. 16*s.*

A Text-book of Electricity and Magnetism

E. R. NOAKES, M.A., F.Inst.P.

This is the new, Third Edition of a book which will meet the need of those taking Intermediate degree courses and the Advanced and Scholarship Examinations of the General Certificate of Education. All the usual topics required at this stage are dealt with, and where necessary calculus is used. Among the special topics discussed are the conduction of electricity through gases, atomic physics and modern views on ferro- and terrestrial magnetism. *Third Edition.* 14*s.*

Comprehensive Inorganic Chemistry

Edited by M. CANNON SNEED, J. LEWIS MAYNARD and ROBERT C. BRASTED

Volume III—The Halogens, by ROBERT C. BRASTED

Comprehensive Inorganic Chemistry is an eleven-volume reference work on the chemical elements and their inorganic compounds. In this Third Volume the significant advances of recent years are fully reflected in a broad treatment of halogen chemistry. Both basic principles and their applications are exhaustively covered, as well as the new processes, methods of production, and the chemistry of compounds which have lately become so important. 35*s.*

The Light Metals Handbook

Text and Tables

GEORGE A. PAGONIS

Light Metals Resarch Laboratory, San José, California

This book simplifies the task of gathering facts and information on aluminium- and magnesium-base alloys. It was written to serve all aircraft, industrial, and civil engineers, fabricators and light metal foundries, as well as men developing engineering specifications. It is published in two volumes, text and tables, bound together in detachable sections. 63*s.*

45% greater capacity

cuts filing costs . . .

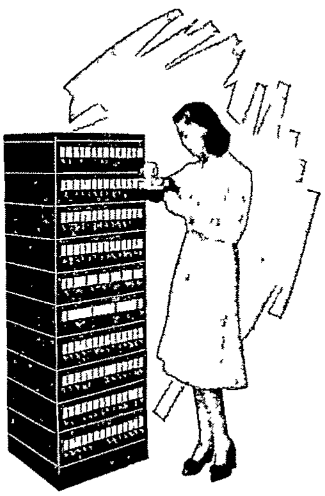
saves floor space

Single "LAB AID" section holding two 1" drawers, two 2" drawers (for wide slides, color transparencies, etc) and two 4" drawers (for lantern slides, cards, etc)

How can a Technicon "LAB-AID" filing cabinet measuring only 19" square by 5" high hold up to 6500 (average) one-inch microslides? The single section illustrated here with its drawers extended will show you why . it's because there are no thick bulkheads between drawers — no space-consuming buttresses, no bulky tracking guides Yet, close-set as they are, every drawer slides straight and true . easily, smoothly, without binding

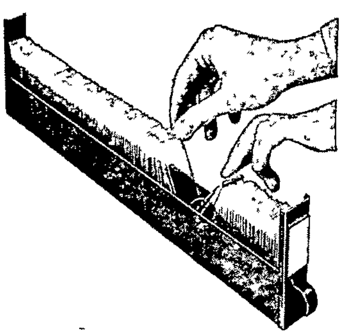
Drawers are freely interchangeable, too, thanks to the unique "LAB-AID" unit-gauge track system, so that you can intermix 1" drawers with 2" drawers (even 4" drawers, if you like) according to your needs

Staunch, fireproof "LAB-AID" units are strongly built of heavy gauge steel for a lifetime of satisfactory use Beautifully finished in olive green enamel, with combination drawer-pulls and label holders Separate bases and finishing cap panels make complete units of any number of sections your filing needs require, expandable at will at any future time.



A stack of ten sections, complete with base and cap panel Interlocking design lets you pile sections right up to the ceiling Staunch 'LAB AID' construction easily bears the heavy weight of solidly packed slides

For filing current slides, the removable spring separator lets you riffle through them as easily as you flip the pages of a book easy to file, easy to find Slip it in when you need it, take it out when you use the drawer for storage filing



TECHNICON Lab-aid laboratory filing cabinets

Technicon "LAB-AID" filing cabinets have long been standard filing equipment in laboratories throughout the world Now made in France, they can be easily imported into the United Kingdom.

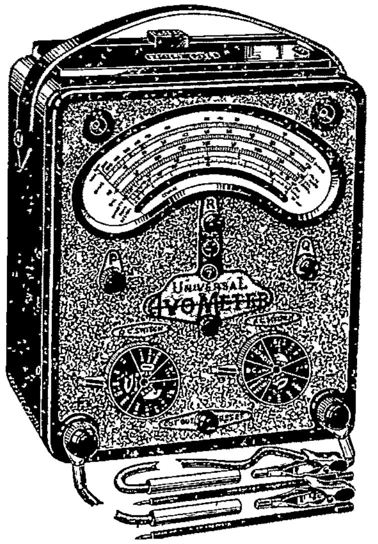
Instrumentally Speaking

Wherever electricity is used in industry, there is a need for electrical measuring instruments. Phenomenal development in the war and post-war years has produced a need for such a multiplicity of instruments of different kinds that there is a prevailing tendency towards the slowing down of maintenance and laboratory work through having too many instruments in use. Incidentally, too much test gear also means too much expense. The answer to such problems is provided by "Avo" MULTI-RANGE instruments.



The Model 7 Universal AvoMeter is a typical example of a modern "AVO" multi-range meter It is a combination A C /D C instrument providing on a 5-inch hand calibrated scale 50 ranges of readings of Current, Voltage, Resistance, Capacitance, Power Output and Decibels The total resistance of the instrument is 500,000 ohms, and its small power consumption and precision accuracy make it the choice of radio, television and electrical engineers throughout the world An external accessory is also available for measuring Power and Power Factor

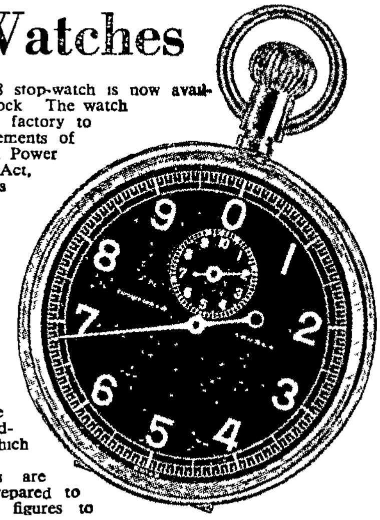
Stop Watches



OUR improved model 308 stop-watch is now available for delivery from stock The watch is specially timed at the factory to conform with the requirements of the Ministry of Fuel and Power (Elec Supply Meters Act, 1936) and the requirements of the N P L for a high grade stop watch with a 1/30th second escapement suitable for laboratory use

The dial is calibrated 0-10 mins the large band making 1 revolution in 10 secs The size of the watch, 22 ligne, with a dial diameter of 1¾ in, allows the use of a very open scale thus facilitating the reading of the sub-divisions which are graduated 1/20 sec

Black or white dials are available and we are prepared to luminise the hands and figures to special order

A comprehensive range of stop-watches is available for all purposes

Under research, sylvicultural research work in the high forest zone has reached a successful stage which will enable results to be placed at the disposal of the working plans branch. Under local authority forestry the introduction of a new system of local government has necessitated a revision of the forest reserve rules and by-laws. Here the necessary amendments have been made in order to enable alterations in the by-laws to be made. The destruction of forest land by farming has increased owing to the high price offered for cocoa; it is estimated to have been 780 square miles a year, and the amount of high forest outside forest reserves now remaining is assessed at 6,327 square miles. Most damage has been done in Ashanti. No control of this farming has yet been achieved, and it is altogether a great blot on the administration in Africa generally—under other governments besides the British.

Three other facts emerge from the report. The control of timber concessions is under the chief conservator of forests. Secondly, plans have been made for the expansion of the training of the subordinate staff which it was hoped to bring into force in 1954. Finally, advice is always available on technical subjects to mining companies and others on the establishment and management of fuel and pole plantations upon which progress is being made in many parts of the country. E. P. Stebbing

J.-S. BAILLY, AN EIGHTEENTH-CENTURY FRENCH SAVANT

In a publication entitled "Jean-Sylvain Bailly, Astronomer, Mystic, Revolutionary, 1736–1793" (*Trans. Amer. Phil. Soc.*, N.S., 44, Part 1, 427–538, 1954. From the American Philosophical Society, Independence Square, Philadelphia 6, Pa., 6 dollars), Edwin Burrows Smith gives an account, including a very comprehensive bibliography and index, of one who was a statesman, astronomer and savant. A member of the French Academy and of the Academy of Inscriptions, Bailly was president of the Third Estate and of the National Assembly and was Mayor of Paris during 1789–91. This meteoric career came to an abrupt end soon after his retirement at Melun, where he was seized, charged with conspiracy and executed in 1793.

Born into an essentially artistic milieu, Bailly abandoned the arts to study Newtonian physics, became a respected astronomer and won wide recognition throughout Europe for his research on Jupiter's satellites. Later on, however, he concentrated on the historical side of the subject, and between 1775 and 1787 he published five large volumes on the history of ancient and modern astronomy. In addition, in three smaller works he tried to retrace the course of man's development, and supported the theory of a primitive golden age. Although his scholarly works brought him many public honours, not only in France but also in four other European countries, he nevertheless found himself involved in a number of scientific and literary quarrels, largely because of his wild speculations on antiquity. Perhaps it was fortunate that he took part in the investigations of Mesmer's pretensions regarding animal magnetism, because this brought him back into contact with controlled scientific inquiry in which men like Franklin, Lavoisier, Guillotin and others played a prominent part, so that after the autumn of 1784 mesmerism rapidly disappeared from Paris, though it continued to be practised in the provinces.

The study of Newtonian physics led Bailly to the belief that scientific precision could be extended to other fields of human knowledge, such as history, law, language, etc., and this view led to a breach with the sceptical philosophers who had little confidence in systematic explanations of immaterial or intangible phenomena. As the author of this biography remarks, "Bailly fell victim to the hobgoblin of *vraisemblance*", in other words, in cases where truth could not be demonstrated, he was prepared to accept the probable explanation. The French Revolution represented the acid test for Bailly's philosophy, for that was the period when the theorist could try the practical application of his ideas, and Bailly's ideas did not survive the test. At the end of the biography, the author pays a tribute to his public work, in spite of its lack of success. "The remarkable aspect of Bailly's public life is not his failure, but the fact that he succeeded so well in coping with the practical problems which were so far removed from his cognizance".

A DETAILED RADIO MAP OF THE SKY

By Prof. J. D. KRAUS and H. C. KO

Radio Observatory, Department of Electrical Engineering, Ohio State University

From observations during the spring of 1954 with the Ohio State University radio telescope, a detailed radio map of the sky has been made. This map (Fig. 1) has sufficient detail to suggest how the sky would appear if our eyes were sensitive to radio waves instead of light. The central region of our galaxy or Milky Way system stands out prominently, as do also a number of localized radio sources such as Cassiopeia *A* and Cygnus *A*.

The contours are lines of equal radio brightness as observed at 250 Mc./s. with the 96-helix antenna of the Ohio State University radio telescope. The observations were made by setting the antenna at a fixed declination for several days. As the earth rotated, a record or profile of the cosmic radio background was then obtained as a function of right ascension for a narrow zone of declination. Scores of such profiles taken at other declinations were combined to produce the map. The co-ordinates are right ascension (α) and declination (δ) (1950.0) and the contours give the apparent radio brightness in units of 10^{-25} W. m.$^{-2}$ (c./s.)$^{-1}$ deg.$^{-2}$. The map gives the observed levels, not being corrected for the antenna pattern. Thus, a minor lobe of the antenna appears as a small rise near the preceding sides of the strong sources Cassiopeia *A* and Cygnus *A*. The elongated shape of these sources is a direct measure of the antenna pattern, which is a fan-beam 1° wide between half-power levels in right ascension by 8° in declination at 250 Mc./s. The minor lobes and elongated shapes are imperfections in the radio map that are analogous to the defects in an image seen with an optical telescope due to the aberrations of the lens. Since the map is a Mercator projection, a localized source near Dec. 0° such as Virgo *A* appears as a more slender ellipse than does a source more remote from the equator such as Cassiopeia *A*.

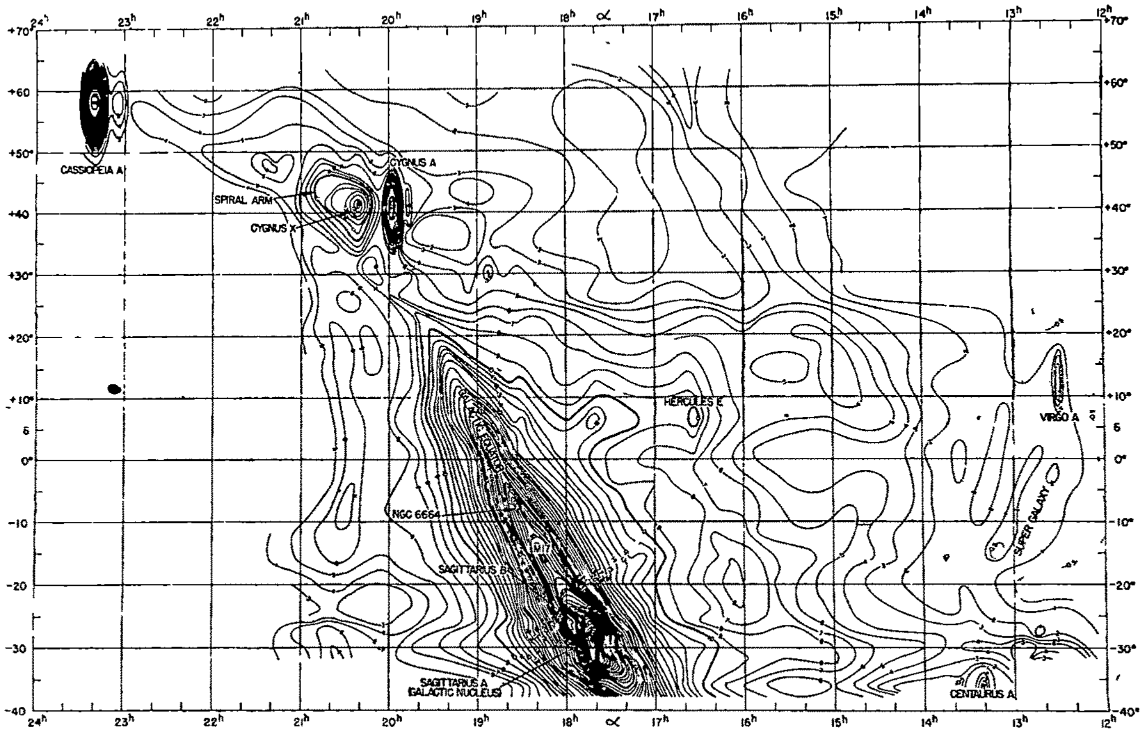

Fig. 1. Map showing the apparent radio brightness of the sky as observed at 250 Mc./s. The contours are lines of equal radio brightness (radio isophotes). Cassiopeia *A*, Cygnus *A*, the central region of our galaxy and its nucleus (Sagittarius *A*) stand out as intense sources. A number of weaker sources are also indicated

Although records were taken continuously, twenty-four hours a day, usually only those obtained during the early morning hours were sufficiently free from interference (solar and terrestrial) to be usable. Thus, the map is restricted to the region between R.A. 12^h and 24^h. The region north of Dec. +65° is not included, due to interference, while that south of Dec. −40° is either close to or below the horizon. Observations are in progress to extend the map to the entire sky observable from Columbus, Ohio, that is, north of about Dec. −40°.

In addition to such well-known sources as Cassiopeia *A* (peak value 46) and Cygnus *A* (peak value 37.5), the map also reveals a number of extended sources such as the one coinciding with the plane of the supergalaxy[1,2] in the region between the localized sources Virgo *A* and Centaurus *A*. The latter source is actually below the lower boundary of the map (at Dec. −43°) but its presence can be deduced from the deviation of the nearby contours.

In constructing the map each profile was arbitrarily adjusted to the same zero or reference-level for all declinations along a line near R.A. $11^h\ 30^m$, the minimum brightness being near this line. Thus, the map may be subject to a slight distortion which would appear chiefly as a small gradient in declination. Also, since the minimum background-level is finite, not zero as assumed, all contour-levels on the map should be increased by this minimum brightness (of the order of 8 map units) in order to give the absolute brightness-level.

Although numerous radio contour maps of the sky have been published, the resolutions have been insufficient to reveal much detailed structure. Two exceptions are the recent maps by Hanbury Brown and Hazard[3] of the Cygnus region and by McGee and Bolton[4] of the region near the galactic centre, both made with 2° × 2° beams. However, both these maps cover only relatively small regions of the sky.

The highest elevation on the map, designated Sagittarius *A*, is presumably the galactic nucleus; it stands out as a sharp spire (peak value 65) superimposed on the general galactic background. The centre of our galaxy is obscured by dust from optical observation, so that a direct observation of the position of the nucleus is of much importance. The equatorial co-ordinates (1950.0) of the galactic nucleus as determined from the map are

$$\text{R.A.}: 17^h\ 42^m\ 48^s \pm 15^s, \quad \text{Dec.}: -28°\ 50' \pm 30'$$

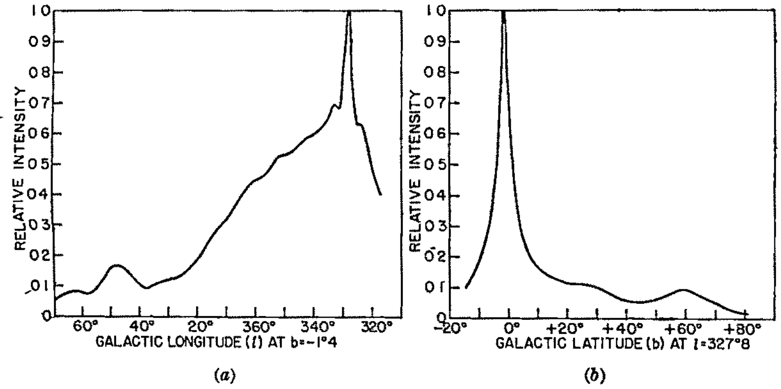
The corresponding galactic co-ordinates (Ohlsson) are

$$l = 327.8°, \quad b = -1.4°$$

Haddock, Mayer and Sloanaker[5], with a $\frac{1}{2}° \times \frac{1}{2}°$ beam at 9.4 cm. wave-length, report a position for this source of $17^h\ 42^m\ 30^s \pm 12^s$ and $-29°\ 01' \pm 5'$. The agreement of the positions is within the error of measurement.

Longitudinal and transverse profiles through the galactic nucleus as obtained from the map are presented in Fig. 2. The ordinates are the relative intensity (or relative brightness). Fig. 2*a* shows the intensity in the plane of our galaxy expressed as a function of galactic longitude at a constant galactic latitude of −1.4°. Fig. 2*b* shows the intensity at right angles to the galactic plane expressed as a function of galactic latitude at a constant galactic longitude of 327.8°.

From the galactic nucleus, which rises as a sharp peak at 327.8°, the longitudinal profile (Fig. 2*a*) has a gradual decrease to about 360° with a somewhat more rapid falling off beyond. This change in slope is probably related to the fact that from about 330° to 360° radiation is observed from the inner spiral arms



(a) (b)

Fig. 2 (a) Longitudinal and (b) transverse profiles through the galactic nucleus showing the observed relative radio intensity as a function of the galactic longitude and the galactic latitude

of our galaxy. From 360° to 40°, and beyond, the direction of observation is outside the inner spiral arms and the intensity falls off more rapidly except for a small peak at about 48°. This peak is presumably caused by radiation from the spiral arm in which we are situated being observed inwardly along the arm.

Fig. 2b reveals the thin structure of our galactic disk as viewed in transverse section. However, residual radio intensity is seen to extend out to large galactic latitudes with small peaks near the galactic latitudes of 30° and 60°.

POSSIBLE SITE AND MODE OF ACTION OF CERTAIN LIPOTROPIC MACROMOLECULES IN TUBERCULOSIS

By Dr. J. E. LOVELOCK and Dr. R. J. W. REES
National Institute for Medical Research, Mill Hill, London, N.W.7

It has been reported that certain macromolecular detergents are effective chemotherapeutic agents against tuberculous infection in mice[1] and in guinea pigs[2]. More recently, Cornforth, Hart, Nicholls, Rees and Stock[3] have shown that the antituberculous effect is confined to members of these series having a high lipophilic/hydrophilic ratio, and that as this ratio is decreased therapeutic activity is reduced and then reversed, so that the more hydrophilic members actually enhance the infection ('protuberculous' effect). The detergents are prepared by forming the polyoxyethylene ethers of a high molecular-weight condensate of *p-tert*-octyl-phenol and formaldehyde. Unfortunately, these antituberculous compounds cause liver damage in animals after prolonged use and cannot at present be considered for use in man. This discovery, however, has stimulated further studies to determine the site and mode of action.

Cornforth *et al.*[1] showed that the detergents were stable *in vivo* and remained within the circulation of the animals for many days. It appears that the activity is a property of the intact substance and is not due to metabolic products of its breakdown *in vivo*[3]. The agents are neither bactericidal nor hæmolytic *in vitro* even at concentrations as high as 2·0 per cent. It seems, therefore, that their activity depends upon some disturbance of the host–parasite relationship rather than a direct toxic action upon the bacteria. This idea receives support from the observation of Hart, Long and Rees[4] that these therapeutically active detergents produce a definite though limited depression of the tuberculin response in tuberculous and BCG-vaccinated guinea pigs. The first indication of a site of action of these substances came from the experiments of Mackaness[5], who showed that suppression of growth of the tubercle bacillus occurred within the host phagocytic cells. Monocytes from rabbits treated for several days previously with one of the chemotherapeutically active agents readily ingested virulent tubercle bacilli, but in contrast to the monocytes of untreated animals, there was little or no multiplication of the bacteria afterwards. Monocytes from untreated animals were not rendered inhibitory to the growth of ingested virulent organisms by the mere suspension of the phagocytic cells in a solution of detergent *in vitro*.

These last observations encouraged experiments to determine whether or not the antituberculous agents actually penetrate the monocytes *in vivo*, and if so to what concentration, and whether they are free or adsorbed upon the surfaces and structures of the cell. Assuming that the detergents do penetrate the cells and are present free at high concentrations, the possibility arises that they might be rendering the organism vulnerable to the destructive agencies of the phagocyte by stripping or modifying a protective lipid outer layer. Experiments, reported here, upon the action of the different detergents towards the hæmolysis of human red cells by thermal shock have a bearing on this point, for the sensitivity of red cells towards hæmolysis on sudden cooling is strongly dependent upon the composition of the lipids of the cell membrane[6,7].

Site of Action

Monocytes were obtained from the peritoneal cavity of mice 24 hr. after the intraperitoneal injection of 0·2 ml. of a mixture of equal parts of 40 per cent 'Lemco' and 20 per cent gum acacia. The monocytes were harvested by washing out the peritoneal cavity with 1 ml. of heparinized saline containing 2 per cent albumin. An equal volume of 0·01 per cent suspension (containing particles of approximately $1\,\mu$ in diameter) of victoria blue, *B*150, was added to the monocyte suspension, and the mixture was then vigorously shaken and incubated at 37° C. Samples were removed at 5-min. intervals and examined under the microscope either as hanging-drops or in slide-cells. The monocytes examined in this way were obtained from mice treated with one of the antituberculous agents and from untreated control animals.

The cells from both the control and the test animals were observed to have ingested the dye particles freely. After a short time, however, the particles within the test macrophages were seen to dissolve and produce discrete circular patches of blue; later the blue patches merged and the whole cell was coloured uniformly. By contrast, the dye particles within the control macrophages remained intact with no trace of dissolution throughout the course of observation. The quantity of dye taken into solution by the detergent was found, by separate experiments, to be directly proportional to the concentration of detergent over the range 0.001–10 per cent. Assuming that the quantity of dye dissolved by a given concentration of detergent is the same within the cell as it is in the test-tube, it is possible to calculate very approximately from the depth of colour of the cell the concentration of detergent it contains. A saturated solution of the dye in 0.01 per cent of a typical therapeutically active detergent gives a blue colour which is only just visible in a layer 100 μ thick. Assuming the thickness of the macrophage is approximately 10 μ, this suggests that the concentration of the detergent within the cell is at least 0.1 per cent, for the cell was visibly blue and it is not certain that sufficient dye had been ingested to saturate the detergent within it.

These experiments suggest that, not only does the cell contain a high concentration of the detergent, but also that it is uniformly distributed with it and is freely available for the solution of the dye and lipid material ingested by the macrophage.

Mode of Action

The macromolecular detergents under discussion are not tuberculostatic *in vitro*, even at concentrations as high as 2.0 per cent. The properties of tubercle bacilli grown in their presence are, however, altered. Most of these detergents promote dispersed submerged growth rather than the normal granular formation[8]. Virulent strains of tubercle bacilli which normally decolorize methylene blue very slowly in the presence of glucose, using the Thunberg–methylene blue technique, do so rapidly when therapeutically active detergents are added (Rees, unpublished work). These effects suggest that the superficial lipid layers of the organism are somehow modified in the presence of these detergents. This might result either from the adsorption of the detergent on to the surface of the organism, or by the solution of lipids from the bacteria within the detergent micelles.

Red blood cells, like tubercle bacilli, have a predominantly lipid outer layer. It is possible to produce modifications in the quantity and proportion of lipids in the membrane of the red blood-cell without causing irreversible damage[6]. Thus the red blood-cell can lose as much as 20–30 per cent of its lipids without hæmolysis. Therefore, although the detergents under consideration are not hæmolytic even at concentrations as high as 2.0 per cent and for periods of exposure as long as 1 hr. at 37° C., this absence of hæmolysis does not necessarily indicate that the cells are unaffected by the exposure. The most simple and sensitive method of determining reversible changes in the lipid composition of the red cell membrane is to observe their sensitivity to thermal shock, that is, hæmolysis on sudden cooling, which is directly related to the proportion of cholesterol to phospholipid in the red cell membrane[7]. The removal of lecithin from the cell increases, and the removal of cholesterol decreases, sensitivity to hæmolysis by sudden cooling. This system thus offers a convenient test for the effect of the different detergents upon the lipid membrane of the red cell and for comparing any such effect with that upon tuberculous infection.

A 10 per cent suspension of human red cells in 0.16 *M* sodium chloride was incubated at 37° C. for 1 hr. with concentrations of the detergents ranging from 0.05 to 10.0 mgm. per ml. At the end of this time an equal volume of 2.4 *M* sodium chloride, also at 37° C., was added to the suspension. After a further 5 min. at 37° C., the tube containing the cells was transferred to a mixture of crushed ice and distilled water and there left for 10 min. The chilled suspension was centrifuged, and the extent of hæmolysis measured in terms of the light absorption of the hæmoglobin released into the supernatant.

Fig. 1 shows the effect on thermal shock of one series of detergents, which were all derived from the same parent resin (*p-tert*-octyl-phenol formaldehyde resin) and are designated by the average number of ethylene oxide units added to each phenolic hydroxyl group of the resin. In the absence of any detergent, 50 per cent of the cells were destroyed by thermal shock. The detergents with ten or twenty ethylene oxide units considerably decreased, whereas the one with thirty units slightly decreased, the severity of the damage by cooling at the lower concentrations used. The detergent of this series with sixty ethylene oxide units increased the damage by thermal shock at all concentrations, and that with ninety units of ethylene oxide only slightly increased the damage. On the other hand, a polyethylene glycol with a molecular weight of 4,000 had practically no effect upon thermal shock.

These results demonstrate that the surface of the red cell is modified after exposure to the detergents. Their interest becomes greater, however, when they are compared with the activity of the detergents

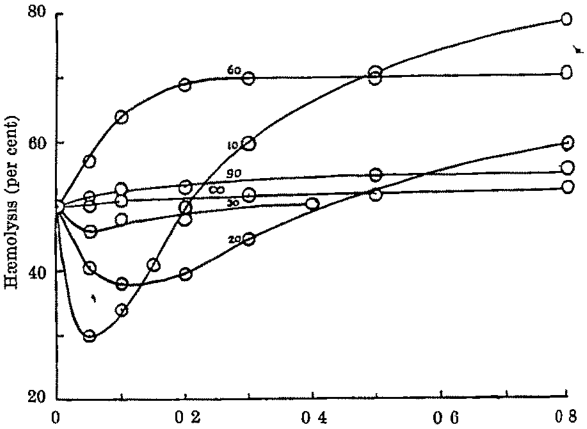

Fig. 1. Effect of exposure for 1 hr. at 37° C. to a homologous series of detergents upon the sensitivity of red cells in 1.2 *M* sodium chloride to hæmolysis by sudden cooling from 37° to 0° C. The detergents tested had 10, 20, 30, 60 or 90 ethylene oxide units per phenolic hydroxyl group. Polyethylene glycol, molecular weight 4,000, is included also to represent a detergent with an infinite number of ethylene oxide units

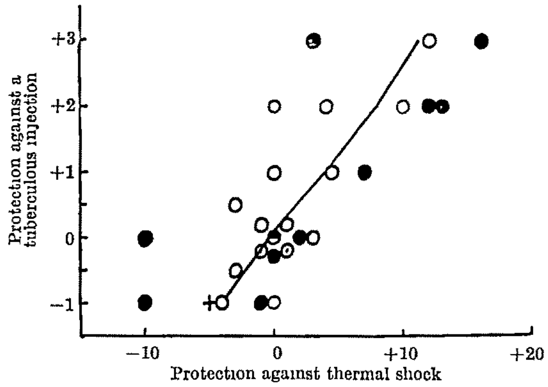

Fig 2 Comparison of the effect of various agents upon the sensitivity of red blood-cells to thermal shock (expressed as percentage change in sensitivity at a detergent concentration of 0 1 mgm /ml) and upon a tuberculous infection in mice The detergents tested included those derived from a linear macromolecule of *p-tert*-octyl-phenol formaldehyde condensate (●), a macrocyclic tetramer of the same condensate (○), suramin (+) and a block copolymer of ethylene and propylene oxides ('Pluronic *F*68') (◓) The curve shows the mean activities towards thermal shock in red cells for each class of activity towards infection

towards infection with tuberculosis *in vivo* The detergents with ten and twenty units of ethylene oxide are both antituberculous, the one with thirty units is inactive and the detergents with sixty and ninety units are 'protuberculous'. The polyethylene glycol is inactive Thus there is a broad correlation between the activity of the detergents towards thermal shock *in vitro* over the concentration range 0–0 2 mgm /ml and their activity towards infection.

Fig 2 compares the activities of twenty-five macromolecular detergents both towards infection with tuberculosis and thermal shock in red blood-cells Mice are infected intravenously with a virulent human strain of *Myco tuberculosis* (*H*37*Rv*) and treated intravenously with the agents on the first, fourth and eighth days after infection The effect of each agent on the course of infection is assessed from the median survival times in the treated and control groups, and its effect in preventing or enhancing infection is finally graded as an arbitrary score between + 3, 2 or 1 (antituberculous), inactive (0) and ('protuberculous') − 1, respectively. The effect in reducing or increasing thermal shock was measured by the technique already described The results shown in Fig 2 are the hæmolysis after thermal shock in 1 2 *M* sodium chloride following exposure for one hour at 37° C. to 0 1 mgm of detergent per ml. of solution Another type of macromolecular detergent, a block copolymer of ethylene and propylene oxides, 'Pluronic *F*68' (Wyandotte Co , Michigan), and a negatively charged high molecular-weight substance, suramin (urea derivative of the aminonaphthalene-sulphonic acid series), are also included for comparison. The block copolymer is inactive in both systems Suramin, on the other hand, has been shown to enhance a tuberculous infection in mice (Hart and Rees, unpublished work) This substance remains intact within the circulation for long periods, and furthermore it is concentrated in monocytes[9]. It is therefore of considerable interest that this substance is active in both our systems, enhancing a tuberculous infection and increasing the sensitivity of red blood-cells to thermal shock

Discussion

The experimental evidence suggests that the detergents are concentrated *in vivo* within the monocytes and that they are present within the cells in sufficient concentration and in a suitably free condition to 'solubilize' lipids ingested by the cell The correlation between the activities of the different detergents towards thermal shock in red cells and towards infection with tubercle bacilli suggests that the activity of the detergents is connected with their ability to modify the membrane lipids of the organism while it is within the macrophage Some light on the possible changes which could occur in the membrane lipids of the tubercle bacillus also comes from the experiments with red cells

The behaviour of the detergents towards red cells is consistent with the notion that the detergents with few ethylene oxide units adsorb or displace cholesterol preferentially from the membrane of the red cell, and detergents with many ethylene oxide units adsorb or displace phospholipid preferentially from the envelope of the red cell This is because the sensitivity of the cell to thermal shock is proportional to the ratio of cholesterol to lecithin in the cell membrane. Preliminary chemical analysis of the lipids of the red cell after exposure to the detergents also lends support for this notion

If the detergents affect the tubercle bacilli and red cells in an analogous manner, then it might be expected that the detergents with few ethylene oxide units per molecule would remove or displace the more hydrophobic lipids of the organisms preferentially This would conceivably render the bacteria more sensitive to digestion within the phagocytic cells The 'protuberculous' activity of the detergents with sixty ethylene oxide units could in a like manner be due to the removal of displacement of the more hydrophilic lipids preferentially, thus rendering the lipid layer of the bacterium even more resistant and impermeable than it is normally These ideas are also supported by the observation that the character of growth and permeability of the organism are changed in the presence of the detergents.

These suggestions are put forward tentatively to provide a working hypothesis for testing other substances It is realized, of course, that even if the suggestions are correct there are other ways in which the host–parasite relationship could be altered by the presence of macromolecules within the phagocytic cells , for example, the suppression or enhancement of enzymic activity of the cell or parasite or both

Whatever is the precise mechanism of action of these agents, it seems very probable that their activity is primarily dependent upon their ability to become concentrated within the monocyte cells, which are themselves known to play an important part in the natural infection

Use of Electronic Digital Computers in Optical Design

ELECTRONIC digital computers in Britain and the United States have been used for the tracing of rays at high speeds through optical systems. The larger machines have enough auxiliary storage, either magnetic drum or tape, to accommodate enormous amounts of information, so that it is possible to carry out extensive numerical investigations concerning lens systems.

During the past year, experiments have been carried out using the University of Manchester electronic computer in the automatic design of optical systems. The optical design problem has been regarded as a minimization problem of a single function φ, which has been called the performance function, with respect to the variable constructional parameters of the system.

The problem is a special one in that the variable-function system is largely ill-conditioned and non-linear, but is less extensive than the general problem because the *n*-dimensional surface concerned has certain known properties due to its optical nature. The performance function φ has been constructed by summing the squares of the maximum moduli of certain blocks of aberration residuals with appropriate scaling or weighting factors. Performance numbers of this sort have no optical significance whatever; they simply relate to the state of the geometrical aberration residuals at points in the minimization process. The precise nature of the function φ does, of course, determine the distribution of residuals at the conclusion of any minimization process; but its nature becomes less important as the calculated residuals become smaller.

Until the present time four principal machine minimization processes have been employed. They are iterative within themselves and iterative with respect to each other. The processes are briefly as follows:

(*a*) *Variable-by-variable minimization.* Here variables are taken singly and adjusted by adding or subtracting small increments to each in turn. The large auxiliary storage of the Manchester machine allows one to store all inter-surface ray-tracing data, so that if a parameter in the middle of a system is altered, the ray-tracing data immediately preceding the altered parameter are 'picked up' and the performance number evaluated very rapidly. If a change in a variable results in an increase in φ, then the sign of the increment is changed and φ recalculated. Should the value of φ fall on any parameter change, then the new value of the parameter is retained and control moves to the next variable in the block or series.

Variable-by-variable minimization is extremely rapid (a 'run' on the surface curvatures of a 'Tessar' takes about twenty minutes machine time), and can be regarded as the basic unit relaxation process of automatic design.

(*b*) *Block relaxation.* What is required at the close of the variable-by-variable process is a method of altering the refraction conditions associated with each variable while the general composition of the system is appreciably unaltered, so that the variable-by-variable process can continue with advantage.

Lens 'bending' can be likened to a block operation of numerical relaxation, it being effected by adding (or subtracting) small equal increments to the surface curvatures of a given lens. In optics, however, the increment is chosen with the particular purpose of improving the overall distribution of residuals.

Automatic block operations can be carried out automatically on from two to *n* variables with two purposes in mind, namely, to reduce the latest value of φ directly, and to change the refraction conditions associated with each variable.

A particularly useful optical block operation is that made by adding small equal increments to all variable parameters, so that the system receives a 'kick' in a certain direction. Throughout this operation and the following operations described, attention must be paid to the configuration of the rays. If the nodal points of the system are taken as reference points, then after each block operation these must be redetermined so that the extra axial rays pass through all systems in a constant manner. In this way only will the resultant values of φ be strictly comparable.

(*c*) *Group operations.* In some cases the variable-by-variable method followed by various block operations leads to an optical system which has a set of residuals all less than those of the original or some intermediate system. It is a simple matter in these circumstances to carry out an optical group operation which is in fact an extrapolation from two systems to a third (usually) better system, that is, to a system which has a still lower value of φ. Group changes can always be made with advantage unless the present lowest value of φ is at a true topographical minimum.

Since the number of variables changed in group operations is considerable and the individual increments generally small, the relation between the extent of the operation and the change in the residuals is largely linear. This fact allows one to 'forecast' a set of residuals without actually calculating them by precise ray-tracing—provided that all 'reference' systems have constant focal length, and an exactly similar ray configuration.

(*d*) *Random operations.* The Manchester machine has a useful facility by which a series of twenty random binary digits are produced by a noise generator; using certain logical instructions, it is possible to add (or subtract) increments to a completely random selection of variables. Should the same parameter be selected *p* times, then that particular parameter receives *p* equal increments. If the value of φ is already low, the general tendency of this random process is to increase φ. The main advantage of increasing φ by random methods is that systems can be evolved for use in group relaxation methods already mentioned. The random process is in fact used for testing whether or not the latest lowest value of φ is in fact a true topographical minimum value.

A programme which incorporates all these methods has been used with success at Manchester. Considerable improvement has been achieved on a 'Tessar' lens which has been in use for many years. The improvement was carried out in a little more than two hours.

It is hoped that a full account of this work will appear elsewhere. I am grateful to the Ministry of Supply for permission to publish this work; thanks are due to the Director and Council of the British

An Interpretation of the Long-Spacing Intensities of Calcium Stearate Monohydrate

THE interpretation of powder patterns of soaps and other long-chain aliphatic compounds which cannot be obtained as single crystals is not easy and is usually ambiguous[1] Samples of calcium stearate monohydrate prepared by D Wallace using the method of Vold, Hattiangdi and Vold[2] were recrystallized from solution in a mixture of propylene glycol and chloroform. The recrystallized soap was in the form of very tiny laths which could be formed into highly orientated sheets by sedimentation or by flotation Such a specimen, mounted on a glass plate, used in a Geiger-counter diffractometer, gives rise to the long-spacing peaks of spacing $d = 50\ 30$ A from planes parallel to the plane of the specimen and no other peaks

The intensities of the reflexions were measured to order 30 No reflexions were found beyond this, although observations were continued beyond order 40 The higher-order reflexions were weak and digital counting was necessary for detecting and measuring them. The intensities, corrected for geometrical factors and sharpened, were used to calculate the linear Patterson function This showed a prominent group of peaks centred at 17 A from the origin, probably indicating that in the structure there are two molecules separated by 17 A more or less parallel to their length This model, assuming that the projection on the long-spacing axis is centrosymmetric, was used for the calculation of structure factors and the corresponding Fourier projection The Fourier projection was refined using a semi-quantitative difference method[3], and it was soon evident that the position of the water molecule, in projection, must be the same as that of the calcium atom The final observed and calculated Fourier projections are shown in Fig 1(*a*) and the corresponding suggested molecular arrangement in Fig 1(*b*) Apart from the 'hole' at $z = \frac{1}{2}$ which is not present in the calculated Fourier projection, the agreement is good The principal peaks and the trough at $z = 0\ 32$ corresponding to the end of the molecule are satisfactorily reproduced in both projections

The nature of the proposed structure with two molecules separated by 16 8 A. parallel to their length restricts ionic bonding between molecules to one direction only, unlike the two-dimensional ionic sheets observed in the soaps of monovalent metals

The powder pattern can be indexed tentatively as a monoclinic unit cell using the methods of Vand[4], with $a = 5\ 70$ A, $b = 6\ 81$ A, $c = 50\ 4$ A, $\beta = 94°$ and possible space group $P2_1$ The observed and calculated densities are 1 07 and 1 04 gm cm^{-3} respectively

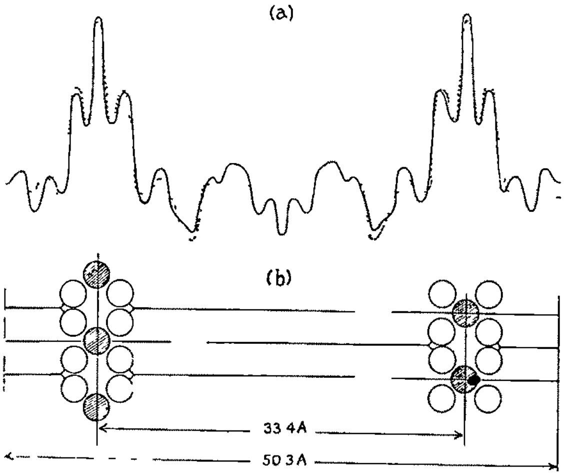

Fig 1 (*a*) Fourier projection on the long-spacing axis the continuous line is obtained using the observed structure factors the broken line using the calculated structure factors

(*b*) Possible type of structure corresponding to Fig 1 (*a*) Calcium atoms, oxygen atoms and hydrocarbon chains are represented by shaded circles, open circles and straight lines respectively The water molecules have not been included in the diagram

The direction of the ionic bonding may be that of the *a*-axis, which is similar in length to the *b*-axis found by Vand, Lomer and Lang[5] in potassium laurate. The molecular cross-section of 19 8 A^2 is greater than in potassium and silver soaps This may be due partly to the restriction of the ionic bonding to one direction.

This work was supported by the U S Office of Ordnance Research under contract *D A.* 04–495 *ord*303 I am grateful to Drs M J Vold and R D Vold for the many stimulating discussions during the course of the work, which was done during the tenure of a Fulbright Travel Grant and a University of Southern California Fellowship.

Formation of Compact Pieces of Grey Tin

IN a recent communication on this subject, Groen[1] described a method of preparing large pieces of grey tin by transforming an alloy of tin containing about 2 atomic per cent of mercury Experiments have been proceeding in this Department with the same end in view, and the purpose of this communication is to describe a possible explanation of this result

In pure tin, the β–α transformation results in the formation of grey tin as a friable powder This condition is the result of cracks, arising during the volume expansion associated with the formation of the α-(grey) tin phase Examination of partially transformed specimens has shown that the cracks may be classified into two groups The first group appear between the islands of grey tin, the second group appear in an irregular manner within the islands themselves The first type of crack can be explained on the assumption that grey tin is mechanically weaker than the white, when two islands of the α-phase meet on the surface, the next layers to be transformed just beneath the surface lever the two islands apart

Microscopic examination of the surface of a partially transformed specimen reveals that each island of α-tin is surrounded by an extensive field of slip lines and kink bands, again due to the surface stresses resulting from the volume expansion The density and coarseness of the slip lines increase as the transformation proceeds, and result in macroscopic buckling of the specimen Since the grey tin is keyed to the α–β boundary, this buckling causes fracture of the weaker α-phase

This second type of crack formation may be suppressed by raising the yield stress of the β-phase, and the most convenient way of doing this is by alloying Indentation hardness tests at room temperature showed that whereas the Vickers Pyramid Hardness number of pure tin was 6 7, that of an alloy containing 2 weight per cent of mercury was 19 8 When this specimen was transformed, few slip lines were observed, and buckling was absent. Cracks of the first type still appeared between the islands, these cracks cannot, of course, be suppressed by this means, but the individual islands were strong and compact. Other alloys with a suitable strength should yield the same result

Structural Breakdown of Cement Pastes at Constant Rate of Shear

For the thixotropic breakdown of materials with time at constant rate of shear, Weltmann[1] proposed the law

$$B = -(\mathrm{d}U/\mathrm{d}t)\,t, \qquad (1)$$

as a result of her work with a rotation viscometer In this equation U is plastic viscosity, t is time from the start of the experiment and B is the coefficient of breakdown with time

Green and Weltmann[2] extended this work and proposed that the thixotropic properties of a material be measured in terms of the three quantities B, M and V, where M is the coefficient of thixotropic breakdown with rate of shear and V measures the change in yield value with decreasing plastic viscosity V is expressed as

$$V = -\mathrm{d}f/\mathrm{d}U, \qquad (2)$$

where f is yield value, but Shapiro[3] has shown that V is simply the value of the rate of shear corresponding to the point of intersection of the various down-curves

It may be shown[4] that under the conditions of Green and Weltmann's experiments, where the rate of shear in a rotation viscometer was increased in equal small steps at equal intervals of time, the constants M and B are one and the same Further, all the equations derived theoretically by Green and Weltmann may be obtained from Weltmann's law alone, without making any further assumptions

If yield value is considered to be constant (which was found to be the case by Weltmann, at constant rate of shear), Weltmann's equation may be integrated and written for the rotation viscometer as

$$T = -B \ln t + \text{constant}, \qquad (3)$$

at constant rate of shear and where T is the torque at time t.

In experiments with a rotation viscometer on the structural breakdown of Portland cement/water pastes at constant rate of shear, I have found[4] that this equation agrees with experiment only over a limited range of torques, points taken after a few seconds deviating widely from it For cement pastes, the decrease in torque can be well represented by the equation

$$T = T_E + (T_0 - T_E)\exp(-B't), \qquad (4)$$

where T_0 and T_E are the initial and equilibrium torques This equation is superior to Weltmann's in fitting the experimental results and has the additional merit of giving a meaning to values of T for $t = 0$ and $t = \infty$ which Weltmann's equation fails to do

In Weltmann's results, her plot of T as a function of $\ln t$ inevitably ignores the value for $t = 0$, and in the case of a pigment suspension D for which she gives full results[1], the next point, for $t = 7$ sec, does not fall on the line The first point which is approximately on the line, at $t = 16$ sec, occurs when 70 per cent of the total drop in torque has already taken place A plot of $\ln(T - T_E)$ against t, on the basis of equation (4), gives two intersecting straight lines Similar results are obtained by plotting Weltmann's results on oils[5] by this method, whereas using her method gives curves of various shapes.

Equation (4) may be derived theoretically[4] by considering the work done in a rotation viscometer and making the assumption that the 'excess torque' $T - T_E$ is proportional to the number of linkages existing According to this theory,

$$B' = (2\pi K\omega^2)/\varphi, \qquad (5)$$

where ω is the average rate of shear, φ is the work done in breaking a single link and $K\omega$ is the constant of proportionality between $T - T_E$ and the number of linkages. It follows that B' is a linear function of ω^2 The experimental results were found to conform fairly well to this prediction They were not adequate to determine the dependence of the constant $(2\pi K)/\varphi$, and hence of φ, on the concentration of the paste, but further work is being done on this point.

In this theory no account was taken of any tendency for a rebuilding of the structure, and it was found that for cement pastes there is no such tendency, at least in a time of the order of that taken for an experiment In this respect this material differs from those with which Weltmann worked, and it cannot be classified as thixotropic

Benzoin as a Fluorescent Reagent for the Detection of Germanium

RECENTLY, we[1] have described a fluorometric method for the detection and determination of germanium, making use of resacetophenone in sulphuric acid or phosphoric acid medium. The test is quite specific, except for the interference of boron. In view of the similarity of the germanic and boric acids thus found, we have investigated the use of other reagents which form fluorescent compounds with boric acid. The reagents described in the literature are flavonols[2], 1-amino-4-hydroxy anthraquinone[3], O-hydroxy carbonyl compounds[4] and benzoin[5]. Among the many compounds tested by us the following have been found to be definitely useful: (1) ω-methoxy resacetophenone, phloro-acetophenone, 4-methoxy-2-hydroxy-benzaldehyde, β-resorcylic aldehyde and salicylaldehyde, which give a greenish-yellow fluorescence; (2) 2-methoxy-3 : 6 dihydroxy acetophenone, 2-benzoyl-phloroglucinaldehyde and 4-methoxy-2-hydroxy-benzoic acid, which give a yellow fluorescence; (3) β-resorcylic acid, orsellinic acid and ethyl orsellinate, which give a violet fluorescence with germanic acid in concentrated sulphuric acid medium.

We have observed that the benzoin reagent described by White and Neustadt[5] for borate also functions as a very sensitive reagent for the fluorometric detection of germanate. It is noteworthy that germanate gives with the benzoin reagent an intense greenish-yellow fluorescence, whereas borate is reported to give a greenish-white fluorescence, beryllium a yellow-green fluorescence and antimony a purplish fluorescence. Zinc gives a green fluorescent compound with benzoin only in the presence of magnesium ions and sodium hydroxide. No other metal or anion is found to give fluorescent compounds with the benzoin reagent. We have found that nitrite, chromate and arsenate quench the fluorescence, whereas silicate somewhat intensifies the fluorescence. Fluoride and nitrate, which quench the fluorescence of germanic acid with the resacetophenone reagent previously described by us, have no effect on the fluorescence with the benzoin reagent.

The fluorescence test with the benzoin reagent is carried out as follows. A saturated solution of recrystallized benzoin in rectified spirit is prepared by shaking an excess of the substance with the solvent at room temperature (28° C.) and filtering; to 5 ml. of this reagent in a quartz test-tube is added 1.0 ml. of a slightly alkaline solution of germanate solution and the mixture made up to 10 ml. with the addition of more rectified spirit. Then the quartz test-tube is exposed to the filtered ultra-violet light from a 'Cenco' black-light source operated on 220 volts a.c. mains. A greenish-yellow fluorescence is observed even when germanium is present in an amount of 10γ. The limit of sensitivity has been found to be 1 100,000. It is evident that the benzoin reagent is more sensitive than the resacetophenone reagent previously described by us. Moreover, benzoin is a reagent easily available, and the method involves its use in alcoholic solution, which is more convenient to handle than the concentrated sulphuric acid medium required for resacetophenone.

We have also observed that the germanate fluorescence with the benzoin reagent persists even after two hours, unlike the borate fluorescence which is described as lasting only for a few minutes by White and Neustadt. The solution, however, acquires a yellow colour on keeping. The benzoin reagent offers possibilities for the fluorometric determination of microgram quantities of germanium.

Chemical Properties of a Plasma Factor accelerating Hæmoglobin Recovery in Bled Rabbits

IT has been shown that plasma of repeatedly bled rabbits—referred to here as 'anæmic plasma'—contains a factor (or factors) which accelerates the recovery of hæmoglobin concentration after a standard hæmorrhage[1] and produces a greater reticulocyte response in receptor animals[2]; when injected repeatedly into normal rabbits, 'anæmic plasma' significantly increases the hæmoglobin concentration, red cell and reticulocyte counts[3]. After boiling 'anæmic plasma' at pH 5.5, the supernatant, separated from the precipitated proteins, is inactive[1].

In this communication we present data showing that the factor responsible for the activity of 'anæmic plasma' can be extracted from the heat-coagulated plasma proteins, with either water or acetone, and we describe some of the steps taken to purify it.

Rabbits were used as experimental animals. The extracts were tested for activity by their effect on the speed of hæmoglobin recovery[1] after a standard hæmorrhage (1 per cent of body-weight). All extraction processes were carried out in an atmosphere of carbon dioxide, as it is possible that oxygen diminishes the activity of 'anæmic plasma'[1].

Fig. 1 shows the recovery from a standard hæmorrhage of rabbits injected with isotonic sodium chloride, normal rabbit plasma, water extract and acetone extract of the coagulated proteins of 'anæmic plasma'. The acceleration of the recovery of hæmoglobin concentration in animals injected with the extracts of anæmic plasma can be noted; the difference from the controls is statistically significant ($P < 0.01$).

Using the same biological test, we have been able to show that the factor in 'anæmic plasma' can be dialysed through 'Cellophane'; that oxygen diminishes the activity of acetone extracts; that the active portion of the dried acetone extracts taken up in chloroform and passed through a standardized alumina column is retained in the top third, whence it can be extracted with acetone. It is possible to repeat the chromatography on columns three times without loss of activity. The active factor in the acetone extracts can be precipitated from aqueous solution with basic copper carbonate, and it is possible to recover the activity from the precipitate by chloroform extraction. It has also been noted that the active factor of 'anæmic plasma' is carried down with both the albumin and globulin fractions after treatment with ammonium sulphate.

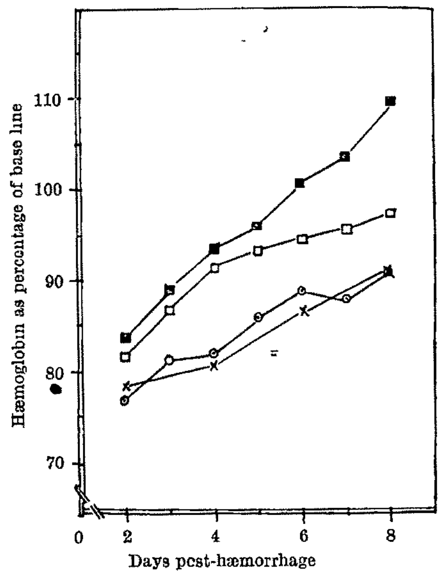

Fig 1 Mean values for hæmoglobin concentration as a function of time, after a standard hæmorrhage (1 per cent body-weight), in the following groups ×——×, 14 rabbits injected with isotonic sodium chloride, ○——○, 16 rabbits injected with normal rabbit plasma, ⊡——⊡, 9 rabbits injected with water extract of 'anæmic plasma', ■——■, 4 rabbits injected with acetone extract of 'anæmic plasma'

The purified acetone extract of 'anæmic plasma' shows (Fig 2) an absorption spectrum in the ultra-violet, similar to that of the extract of 'anæmic urine' It is interesting to note that exposure to oxygen—which diminishes the activity of the extract—changes the ultra-violet absorption spectrum notably However, further chemical purification is necessary before it can be determined whether the ultra-violet absorption spectrum is characteristic of the active factor in 'anæmic plasma' or is due to impurities

Preliminary chemical studies, carried out on purified acetone extracts, show that these only give a positive colour reaction with sudan IV (fatty acid esters) and negative reactions with ninhydrin (amino-acids), mercuric nitrate reagent (purines), and ammoniacal silver nitrate (sugars) on Whatman No 1 paper

Our observations suggest that the factor isolated from 'anæmic plasma' is not identical with the 'erythropoietic hormone' isolated by Contopoulus *et al*[4] from sheep anterior pituitary, which is probably a polypeptide

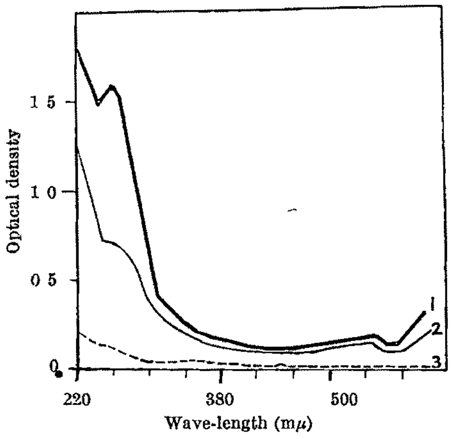

Fig 2 Ultra-violet absorption curve of purified acetone extract of 'anæmic plasma', curve 1 before, and curve 2 after, exposure to oxygen Curve 3 refers to a blank experiment

Further details of the extraction processes and results of the biological tests will be published elsewhere. This work was aided by a grant from the Consejo de Investigación Científica de la Universidad de Concepción We thank Messrs A. Fernández and H Varela for technical assistance

Reconstruction of Coupled Phosphorylation in the Succinic Oxidase System

Calcium ions are known to inhibit oxidative phosphorylation in isolated mitochondria As reported previously[1], in the case of substrates oxidized via diphosphopyridine nucleotide, this inhibition can be reversed by the addition of the pyridine nucleotide, adenosine triphosphate and manganous ions Treatment with the pyridine nucleotide alone partially restores only the respiration, but addition of all three factors is necessary in order to re-establish both oxidation and phosphorylation

The phosphorylation accompanying the oxidation of succinate to fumarate is likewise inhibited by calcium treatment, but, since pyridine nucleotides are not involved in this reaction, the oxidation does not become dependent on the addition of the co-enzyme Calcium treatment thus produces a mitochondrial system catalysing the single-step oxidation of succinate. The addition of adenosine triphosphate and manganous ions to such a system results in a coupled phosphorylation at a phosphorus to oxygen ratio (moles of esterified phosphate to atoms of oxygen consumed) of about unity.

Mitochondria were obtained from rat liver, homogenized in sucrose–versene (0 25 and 0 01 M, respectively) and washed once with the same solution The preparation from one liver was suspended in 20 ml of a saline-buffer solution (pH 7 5) containing potassium chloride, potassium phosphate, adenylic acid and glucose, in concentrations specified in Table 1. The suspension was supplemented with yeast

Table 1 Effect of Calcium Ions on the Oxidation of Different Substrates in Rat Liver Mitochondria

Each Warburg vessel contained substrate, 30 micromol , orthophosphate, 76 micromol , adenylic acid, 5 7 micromol , glucose, 200 micromol , potassium chloride, 230 micromol , magnesium chloride, 10 micromol , yeast hexokinase (prepared and diluted as described in ref 1), 0 1 ml , calcium ions (where indicated), 1 15 micromol pH 7 5 Final volume, 2 5 ml Gas phase, air Temp , 30° C Substrate added from side-arm after 5 min of incubation Total incubation time, 29 min

hexokinase and magnesium chloride and diluted with isotonic potassium chloride to 25 ml. 2 ml. of this suspension was pipetted into Warburg vessels and incubated for 5 min., before addition of the substrate from the side-arm.

If this pre-incubation is performed in the presence of calcium ions (5×10^{-4} *M*), the system loses its ability to oxidize those substrates requiring the participation of pyridine nucleotides, while it is still capable of oxidizing succinate. This is illustrated in Table 1. The nearly theoretical molar relationship between succinate and oxygen consumed (Fig. 1) substantiates the fact that we are here dealing with the single-step oxidation of succinate to fumarate.

In the above system no esterification of orthophosphate accompanies the one-step oxidation of succinate (Table 2). The effect of added adenosine triphosphate and manganous ions is shown in this table. Adenosine triphosphate alone, when added in sufficiently high concentration (the factors determining this critical concentration of adenosine triphosphate are under further investigation), induces a phosphorylation at a maximum phosphorus to oxygen ratio of about unity. Manganous ions alone, at the concentration tested, had no effect; but the involvement of manganese in the phosphorylative mechanism is indicated by the fact that it potentiates the effects of limiting concentrations of adenosine triphosphate.

Inactivation and Activation of Liver Phosphorylase

THE level of phosphorylase in liver slices represents a balance between inactivation and resynthesis of the active form; epinephrine and glucagon rapidly increase the amount of active phosphorylase in preincubated liver slices[1,2]. In order to study the nature of the change in the phosphorylase molecule, liver phosphorylase and the enzyme inactivating it from dog liver have been prepared in purified form. The liver phosphorylase was purified approximately 400-fold, a value higher than previously reported[3]; this purified enzyme was very soluble in water and when inactivated enzymatically showed little or no activity when tested in the presence of adenylic acid. The inactivating enzyme from dog liver was also purified about 400-fold, and this purified enzyme was sufficiently active for microgram quantities to be used in most experiments. Preliminary tests using several proteins as possible substrates have revealed no proteolytic activity.

In searching for possible small fragments released during inactivation, liver phosphorylase inactivated enzymatically was dialysed and the dialysates were analysed. Phosphate was found in the dialysate of liver phosphorylase fractions incubated with the inactivating enzyme, and identical values were found when measurements were made for stable phosphate, or for phosphate as determined by the method of Fiske and SubbaRow[4], or by the Lowry–Lopez method[5]. The phosphate present in the liver phosphorylase was not released when liver phosphorylase was precipitated with cold trichloroacetic acid, so subsequent analyses were conducted by sampling reaction mixtures into trichloroacetic acid and measuring phosphate released enzymatically in the trichloroacetic acid supernatant. Fig. 1 shows the results of such an experiment where the enzymatic inactivation of liver phosphorylase is accompanied by a release of phosphate. 9.5 mgm. of liver phosphorylase in 1.3 ml. of water was incubated with and without 0.038 mgm. of inactivating enzyme (IE), which had been purified approximately 400-fold. At the times indicated along the solid lines, 0.01-ml. aliquots were removed and were assayed for liver phosphorylase activity in a test system which contained adenosine-5-phosphate. At the times indicated along the broken lines, 0.2-ml. aliquots were treated with trichloroacetic acid, and the supernatants after centrifugation were analysed for phosphate. Results are expressed as micrograms of phosphorus released per 9.5 mgm. of liver phosphorylase. The inactivating enzyme alone released no measurable amount of phosphate into trichloroacetic acid supernatants.

Using both the dialysis and trichloroacetic acid precipitation techniques, about 0.25 µgm. phosphorus was found to be released per milligram of liver phosphorylase, or 31 gm. phosphorus per 124,000 gm.

liver phosphorylase Preliminary studies using several other phosphorus-containing compounds, such as *p*-nitrophenyl phosphate, α-glycerophosphate, or sodium pyrophosphate, showed no phosphate to be released by the inactivating enzyme from liver

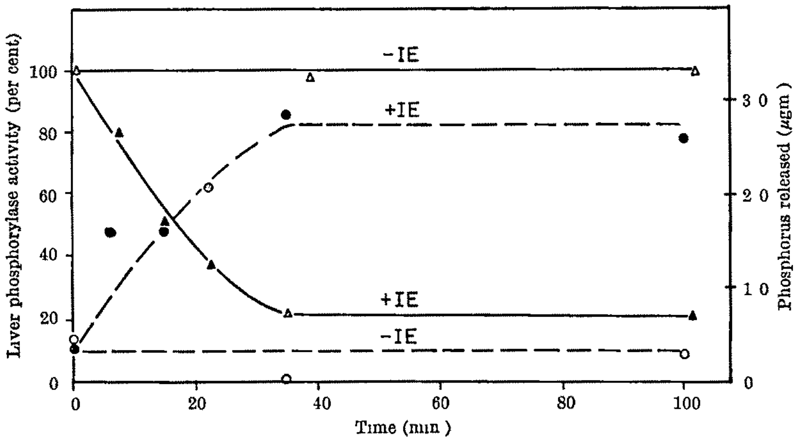

Fig 1

Recent experiments with liver slices have indicated a rapid incorporation of radioactive phosphate into liver phosphorylase Radioactive liver phosphorylase was prepared by incubating liver slices aerobically or anaerobically in the presence of radioactive phosphate and was afterwards purified about 400-fold on a protein basis The incorporated radioactivity was not released when the liver phosphorylase was precipitated with cold trichloroacetic acid, but the radioactivity was released into the trichloroacetic acid supernatant after enzymatic inactivation of liver phosphorylase with the inactivating enzyme In a single preliminary experiment the effect of epinephrine on the incorporation of radioactive phosphate has been investigated The addition of epinephrine to slices after incubation for 30 min increased the amount of active liver phosphorylase within 10 min. to a level well above that of the control without epinephrine, this was paralleled by an increased incorporation of radioactive phosphate into liver phosphorylase

In summary, phosphate is liberated from purified liver phosphorylase as it is inactivated enzymatically, radioactive phosphate is incorporated into the phosphorylase of liver slices These experiments with slices suggest that the observed enzymatic release of phosphate from purified liver phosphorylase is related to a physiological mechanism concerned with the activation and inactivation of liver phosphorylase in intact cells

A New Amino-Acid from Apples

In an earlier paper[1], two unidentified amino-acids in apples were reported Of these, one (*A*) has now been isolated and shown to have the empirica formula $C_6H_{11}NO_3$ It is tentatively suggested that the substance is 4-hydroxy-methylproline.

The substance was extracted with 75 per cent ethanol from 880 lb of Granny Smith and Delicious apple tree prunings which were dormant, without expanded leaves Purification and separation were carried out with resins ('Zeo-Karb 215' and '225') and a cellulose powder column The unknown was obtained as a hydrochloride, converted to the free base by displacement from 'Zeo-Karb 225' with *N* ammonium hydroxide and was crystallized from a saturated hot aqueous solution to give white micro crystals (Found C, 49 41 H, 7 65, N, 9 85, O, 33 2 Calc for $C_6H_{11}NO_3$ C, 49 64, H, 7 64, N, 9 65, O, 33 07 per cent)

A final yield of 0 08 gm was obtained (quantitative recovery was not attempted) The substance is readily soluble in cold water, insoluble in absolute ethanol and melts with decomposition at about 250° C The unknown gives a yellow colour with ninhydrin and a blue colour with isatin, similar to the colours given by proline The isatin spot does not turn red on being sprayed with Ehrlich's reagent[2] The hydrochloride of the unknown is soluble in water, and in absolute methanol, ethanol and propanol It is insoluble in acetone and ether, which precipitate it from solution as an oil

The analysis, assuming 1 atom of nitrogen, could fit a hydroxy-methylproline or a hydroxy piperidine derivative, but the colour reactions with ninhydrin and isatin and the general chromatographic behaviour (on paper and ion exchange columns) favours the former possibility General evidence consistent with this interpretation is (1) secondary nitrogen was indicated by (*a*) positive test with Feigl's reagent[3], and (*b*) the unknown being recovered unchanged after hydrolysis of the compound formed by reaction with nitrous acid

$$\rangle NH + HNO_2 \rightarrow \rangle N{-}NO \xrightarrow[H_2O]{HCl} \rangle NH.$$

(2) a Kuhn–Roth C—CH_3 test was negative

The suggested structure requires further verification The infra-red spectrum of the unknown is now being examined by other officers of this Division and 4-hydroxy-methylproline is being synthesized by the Department of Organic Chemistry, University of Sydney

I am indebted to officers of the Victorian Department of Agriculture for providing the prunings, and to the following members of the Commonwealth Scientific and Industrial Research Organization Mr P Hunter, Division of Industrial Chemistry, for carrying out the large-scale extraction, Dr W Zimmerman, Division of Industrial Chemistry, for the micro-analysis, Miss M V Haas, for technical assistance, and Dr J. R Price, Division of

Industrial Chemistry, and Dr H S McKee, Plant Physiology Unit, for helpful advice [See also Hulme, A C., *Nature*, December 4, p 1055 (1954)]

Infra-red Spectra of the New Proline Derivative from the Apple

IN the work of McKee[1] and of Hulme[2] on apple, two substances have been isolated One of these, from apple peel[2], has been referred to as proline substituted, probably on the same carbon, with methyl and hydroxyl groups The other, from apple twigs, has been referred to by McKee[1] and described above by Urbach as 4-hydroxy-methyl proline, that is, the hydroxyl group is on the methyl side-chain

Samples of the original materials isolated by these authors became available in this laboratory They were therefore subjected to infra-red analysis using the potassium bromide disk method The resulting

evidence

wo sub-

quency 3,400–3,200 cm $^{-1}$) occurs in proline (ref 3, p 208). (3) The band at 3 1 microns (frequency 3,400–3,200 cm $^{-1}$) is characteristic of an imine (ref 3, p 213)

To this point the evidence, though consistent with the substance being a proline substituted with both methyl and hydroxyl groups, does not distinguish between the alternative structures suggested by Hulme and by Urbach While the analysis of these curves, following Bellamy[3], may seem to favour the tentative conclusion of a hydroxyl linked directly to carbon in the ring, it is obvious that a decision awaits other evidence, such as that of synthesis and comparison of infra-red curves for other model compounds

The observations reported above were made possible through the Grasselli Grant to Cornell University for work being directed by one of us (F C S)

Consideration of the Vi-phage Types of *Salmonella typhi* on a Structural Basis

lished work[1a,b,c] has indicated that
ypes of the typhoid bacillus owe
actions with the adapted prep-
the carriage of temperate

to the various types can be divided into two groups those which are modified in phenotype only and revert to phage A when propagated on Type A, and those which present the characters of genotypic or host-range mutants, this being a permanent change conditioned by the Vi-types on which they have been grown. Members of the latter group retain the power to attack the types on which they have been propagated whatever subsequent phenotypic adaptations they may undergo The broad rule has been established that the non-lysogenic types of *Salm typhi* impose only a phenotypic change on Vi-phage II, whereas the lysogenic types produce a genotypic alteration. There are, however, several exceptions to this rule

The artificial replication of naturally occurring Vi-types can be effected by lysogenizing non-lysogenic types with type-determining phages[1a,b,c] For example, Type F_2, which carries phage f_2, can be made by lysogenizing Type F_1 with phage f_2 These artificially prepared types are indistinguishable from those occurring naturally It has recently been found convenient to consider the lysogenically determined Vi-types in terms of the complex non-lysogenic type plus type-determining phage Thus, using the example given above, Type F_2 would be designated $F_1(f_2)$, where the symbol in parentheses indicates the phage carried Such a nomenclature gives a structural formula which shows the phylogenetic relationships of the Vi-types concerned. The types of *Salm typhi* that will be lysed by an adapted phage can be predicted from the structural formula of the type on which the adaptation has been carried out For example, Type 33 = $C(d_6)$ Phage d_6 is the determining phage carried by Type D_6, which is structurally $A(d_6)$. Vi-phage II adapted to $C(d_6)$ acquires simulta
range of phage C plus that of ph
an adaptation to $C(d_6)$ will b

Table 2

Starting phage	Structural formula of lysogenic type on which the starting phage was grown	Non-lysogenic type on which starting phage is propagated	Predicted type of resulting phage	Structural formula of type to which new phage corresponds
F_2	$F_1(f_2)$	A	29	$A(f_2)$ = Type 29
F_2	$F_1(f_2)$	C	30	$C(f_2)$ = Type 30
29	$A(f_2)$	C	30	$C(f_2)$ = Type 30
30	$C(f_2)$	A	29	$A(f_2)$ = Type 29
D_6	$A(d_6)$	C	33	$C(d_6)$ = Type 33
33	$C(d_6)$	A	D_6	$A(d_6)$ = Type D_6
26	$A(26')$	E_1	31	$E_1(26')$ = Type 31
31	$E_1(26')$	A	26	$A(26')$ = Type 26

Table 1 shows the application of the structural formulæ to the known lysogenically determined types

A lysogenically determined type will not be sensitive to Vi-phage II adapted to another type carrying the same or a similar determining phage, unless its non lysogenic precursor is the same as that of the other type (for example, Type C is the common precursor of Types 30 and 33 in the illustration given earlier) or is the universally sensitive Type A Thus Type F_2, which has the structural formula $F_1(f_2)$, is resistant to phages 29 and 30—both adapted to types carrying phage f_2—because the non-lysogenic precursors of Types 29 and 30 (A and C respectively, see Table 1) cannot modify Vi-phage II so that it will lyse Type F_1 Thus, the difference between Vi-phage II adapted to Types F_2, 29 and 30 is the same as the difference between this phage adapted to Types F_1, A and C respectively, and neither phage A nor phage C will lyse Type F_1.

When Vi-phage II has been gr a lysogenic type that
phenot

host-range mutants that pre-exist in concentrated preparations of phage *A*.

Effect of Aeration on the Formation of Nitrate-reducing Enzymes by *Ps. aeruginosa*

Skerman[1], using a recording polarograph, reported that an actively growing culture of *Pseudomonas* was saturated with oxygen only when the broth was agitated by a stirrer revolving at 500 r p m , and that under such conditions nitrate was not reduced In cultures stirred at 100, 200 or 300 r p m , there was a rapid drop in the oxygen tension and nitrate was then reduced.

Experiments carried out in this laboratory, using suspensions of *Ps aeruginosa* N C T C 6750 grown in 0 2 per cent nitrate broth and aerated by continuous shaking, suggested that aerobic denitrification occurred in some of the cultures The inability of most of the shaken cultures to reduce nitrate anaerobically when tested in Warburg manometers suggested that oxygen was inhibiting the formation of nitrate-reducing enzymes, the occasionally active suspension being presumably due to incomplete aeration. The only obvious variables to account for the occasionally active cultures were differences in the size and shape of the flasks used Therefore an experiment was carried out to determine the effect of altering the size and shape of flask on the denitrifying activity of the suspension Six different flasks (Fig 1, 1–6) were used

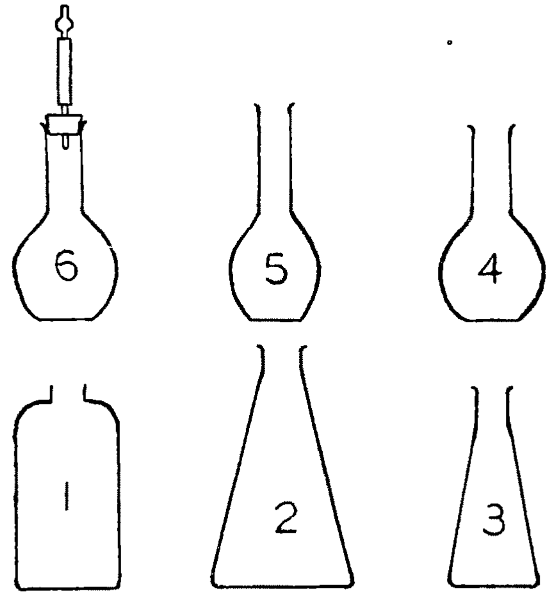

Fig 1 1, One-litre bottle used for intravenous glucose administration 2, One-litre Erlenmeyer flask 3, 500-ml Erlenmeyer flask 4, 500-ml Florence flask 5, 490-ml Florence flask 6, 500-ml Florence flask fitted with a tight-fitting rubber bung, tubing and clip for replacing the air with nitrogen

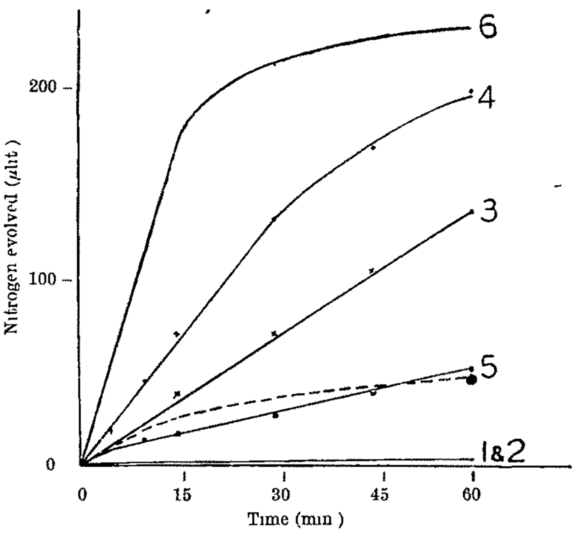

Fig 2 Evolution of gaseous nitrogen by suspensions 1–6 under anaerobic conditions The broken line represents endogenous gas evolved by suspension 6

Each flask, containing 200 ml nitrate broth, was inoculated and shaken at 37° C for 16 hr The growth was washed twice with saline and resuspended in *M*/15 phosphate buffer, *p*H 7 4, and standardized turbidimetrically The suspensions numbered 1–6 were tested for nitrogen evolution in Warburg manometers using 0 1 ml of *M*/5 sodium nitrate as the source of oxygen and yeast autolysate as the hydrogen donor[2] The air was replaced by oxygen-free nitrogen, a small stick of yellow phosphorus being included in each cup to remove all traces of oxygen

Suspension 6 reduced the nitrate quantitatively to nitrogen gas in about 15 min at the rate of 58 µl /hr / mgm. of wet-weight of cells Suspensions 1 and 2 showed no denitrifying activity and the rates for suspensions 3, 4 and 5 were 11, 15 and 4 5 µl nitrogen/ hr /mgm of wet-weight of cells respectively The gas evolution by the last three suspensions showed that aeration of flasks 3, 4 and 5 was insufficient to prevent the formation of nitrate-reducing enzymes, although the suspensions showed a much lower activity than the anaerobic control Aeration of the cultures in flasks 1 and 2 was enough completely to inhibit the formation of the nitrate-reducing enzymes The larger volume of air and the more violent agitation of the broth in flasks 1 and 2 resulted in more efficient aeration of the cultures compared with those in flasks 3, 4 and 5 Hence the efficiency of aeration of the culture determined the ability of the suspension to reduce nitrate to gaseous nitrogen when tested under anaerobic conditions

This work indicates that reports of aerobic denitrification by various workers[3] using shallow layers of undisturbed media and also deeper layers aerated by bubbling air through the medium may well be due to failure to meet the high oxygen demand of a rapidly multiplying aerobic organism in a liquid medium Many methods of forced aeration in deep cultures were insufficient to maintain oxygen saturation, especially as the growth became denser, and it was then that denitrification was detected, apparently under aerobic conditions

In addition to the size and shape of the flask, other factors such as the volume of medium, the organism and the speed and amplitude of shaking may affect the aeration The work is being continued with several other strains of denitrifier and the results will be described in detail elsewhere

The Long-finned Tunny, *Germo alalunga* (Bonnaterre), in British Seas

MR S S PICKARD has kindly supplied details and a photograph of a long-finned tunny, albacore or germon, *Germo alalunga* (Bonnaterre), found alive in a shallow pool at low tide at Morecambe, Lancs, on August 14, 1954 The fish measured 32 in from snout to caudal fork, had a pectoral fin 12 in in length and weighed 22 lb This is only the twelfth British record of the species, the other eleven being as follows, the numbers indicating the footnote references 1–11 (1) "Several years" prior to 1846 (Mount's Bay, Cornwall), (2) summer of 1846 (Mount's Bay, Cornwall), (3) March 13, 1861 (Chesil Beach, Weymouth, Dorset), (4) August 26, 1865 (mouth of River Exe, Devonshire), (5) October 25, 1897 (Silloth, Solway Firth), (6) June 1900 (off the Orkney Is), (7) autumn 1901 (coast of Wexford), (8) August 1914 (Dugort, Achill Island, Co Mayo), (9) November 1932 (Lochgoilhead, Firth of Clyde), (10) June 20, 1934 (Kilmun, Holy Loch, Firth of Clyde), (11) September 16, 1947 (west of Dingle, Co Kerry)

Germo alalunga is essentially a warm-water species, ranging widely through the Atlantic from Massachusetts to the West Indies and from the Orkneys to the Cape of Good Hope, and entering the western Mediterranean Off Spain, in the Bay of Biscay and towards the approaches of south-west Ireland, there is a considerable fishery for it, but Moreau[12] gives the Bay of Morlaix as the eastern limit along the Breton coast and states that the germon is extremely rare in the Channel beyond there Saemundsson[13] gives no records for Iceland, nor Smitt[14] nor Andersson[15] for Scandinavia A solitary 'record' for Holland ascribed to van Bemmelen[16] by several authors proves to be unfounded van Bemmelen writes generally of unidentified tunny in the North Sea and mentions two European species, but with no positive identification or presumption of *G alalunga* in Dutch waters

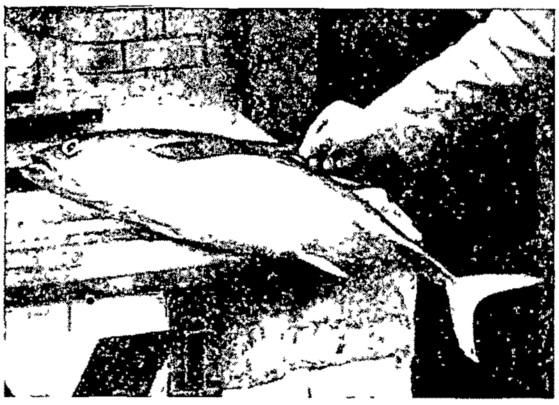

Fig 1 Long-finned tunny, stranded at Morecambe on August 14, 1954

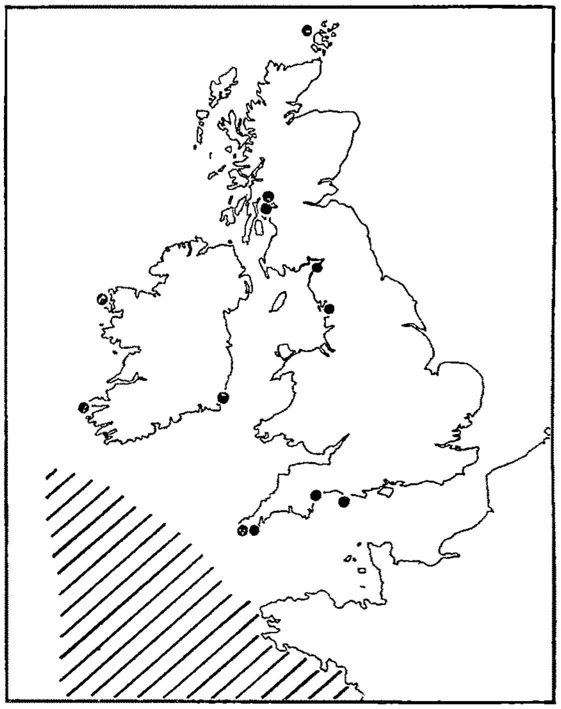

Fig 2 Distribution of *Germo alalunga* in British waters The cross-hatched area shows the approximate northern limits of the French germon fishery

This, then, is a fish which is near the northern limits of its range in British seas, and its occurrence is of interest in relation to modern studies[17] on the effects of climatic fluctuations on the distribution of northern faunas The excellent work on the food of the germon by Legendre[18] and by Bouxin and Legendre[19] will serve equally well as an introduction to its general biology and to relevant literature

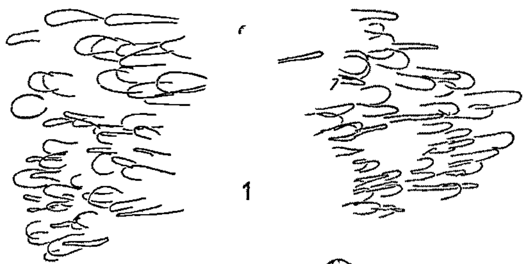
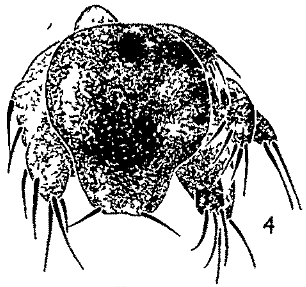
Triploid Nauplii of *Calanus finmarchicus*

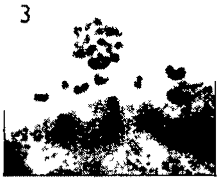
WHILE examining the chromosomes of developing eggs of *Calanus finmarchicus*, it was noticed that on two occasions a proportion of the eggs of a clutch were triploid with 51 chromosomes, the haploid number being 17 It has been observed also that clutches of eggs of *Calanus finmarchicus* are occasionally seen in which one (rarely more) of the eggs is much larger than sister eggs of normal size In order to find out whether these large eggs are triploid, one just about to undergo the fourth cleavage was fixed in acetic alcohol immediately the nuclear membranes disappeared, and a squash was made with aceto-carmine The chromosomes were rather faintly stained, but in one of the divisions, as shown in Fig 1, 102 chromosomes could be counted in anaphase, 51 on each side

Most of the outsize eggs developed with their smaller fellows up to about the gastrula stage quite normally, but as a rule they did not hatch with the rest and died later Up to at least the anaphase of the third cleavage, however, the triploids divided synchronously with their diploid sisters On a very few occasions the large eggs have actually hatched into nauplii correspondingly large in size One of these appeared to be quite normal except for its gigantism, but in an attempt to rear it further this specimen was lost A second specimen which hatched (Fig 4) was a monster with an abnormal first antenna and the second antenna and mandible united on one side A normal nauplius is shown in Fig 5 drawn to the same scale for comparison

There are several ways in which a triploid embryo may arise, but most of them are ruled out here That large size is often associated with a polyploidy is well known, but in this example the large size of the egg at the time it is laid indicates that the polyploidy must have arisen earlier than the time of laying A normal egg is laid when the chromosomes are arranged on the metaphase plate of the first maturation division, 17 bivalents, in the form of rings, being clearly discernible (Fig 2) It is not until several minutes after the egg is laid that the first polar body is produced (Fig 3) If polyploidy were due to the union of a haploid ovum with a diploid sperm, or with two haploid sperms, this event would take place too late to account for the large size, and it seems unlikely that the large size would be responsible for polyspermy One possibility which remains is that the triploid has resulted from the union of a normal, haploid sperm with a diploid egg-cell The most usual way for diploid egg-cells to arise is by failure of reduction at meiosis, but again this would take place too late to affect the size of the egg A diploid egg could arise by reduction from a tetraploid oocyte, the tetraploid condition resulting from the division of the chromosomes of one of the oogonia without a corresponding division of the nucleus This, if it occurred sufficiently early, would account not only for the large size of the eggs, but also for the fact that these do not always occur singly in a clutch of eggs On this hypothesis we might expect to find 1, 2, 4, 8 or some other power of 2 such eggs in a clutch From one of the two clutches of eggs in which triploidy was first observed a sample of nineteen eggs was examined cytologically, of these eleven were diploid, four were triploid and four uncountable From the other abnormal clutch sixteen were examined, two being diploid, two triploid and the rest uncountable Unfortunately, the sizes of these eggs were not noted On the rare occasions when large eggs have been noticed, they have usually occurred singly Once there were four larger than the rest, but three of them were smaller than those usually distinguished as 'large' This hypothesis might also account for the poor viability of the embryos, for with four identical chromosomes of each of the seventeen types, a regular reduction division to 34 bivalents would be a rare occurrence, as tetravalents and trivalents would be formed as well as bivalents However, on all occasions on which accurate counts have been made of the anaphase chromosomes of a dividing triploid cell, precisely 51 chromosomes have been counted on each side







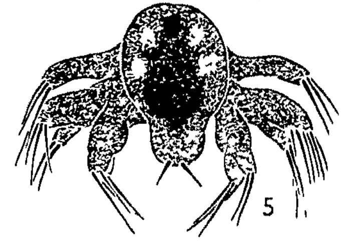


Fig 1 Fourth cleavage of triploid nauplius showing 51 chromosomes on each side at anaphase × 530

Fig 2 Metaphase I from a normal egg immediately after laying, showing 17 bivalents × 670

Fig 3 First polar body formation, 5 min after the egg was laid × 670

Fig 4 Triploid nauplius soon after hatching × 120

Fig 5 Normal nauplius × 120

All figures from preparations preserved in the British Museum (Natural History)

Alternatively, the large egg may be a binucleate one, each nucleus undergoing a normal meiosis in which only bivalents would be formed A triploid embryo would then result from the fusion of the two haploid egg nuclei with one sperm nucleus

It might be possible to distinguish between these hypotheses if a large egg could be examined at the stage corresponding to Fig 2, but these eggs are so rare that we have not yet found one sufficiently soon after it was laid to be able to do this

Structure of *Vertebraria*

A REMARKABLE completely fusinized specimen of *Vertebraria indica* Royle (Fig. 1) has recently been collected from the south of Jhagrakhand Colliery (Middle Permian) in the Central Province of India. The rock bearing the fossil is a piece of greyish shale. It shows the characteristic rectangular blocks with two longitudinal and a number of transverse grooves of *Vertebraria*. The fusinized rectangular blocks are sometimes as thick as ½ in. This type of well-organized fusinized fossil is not very common.

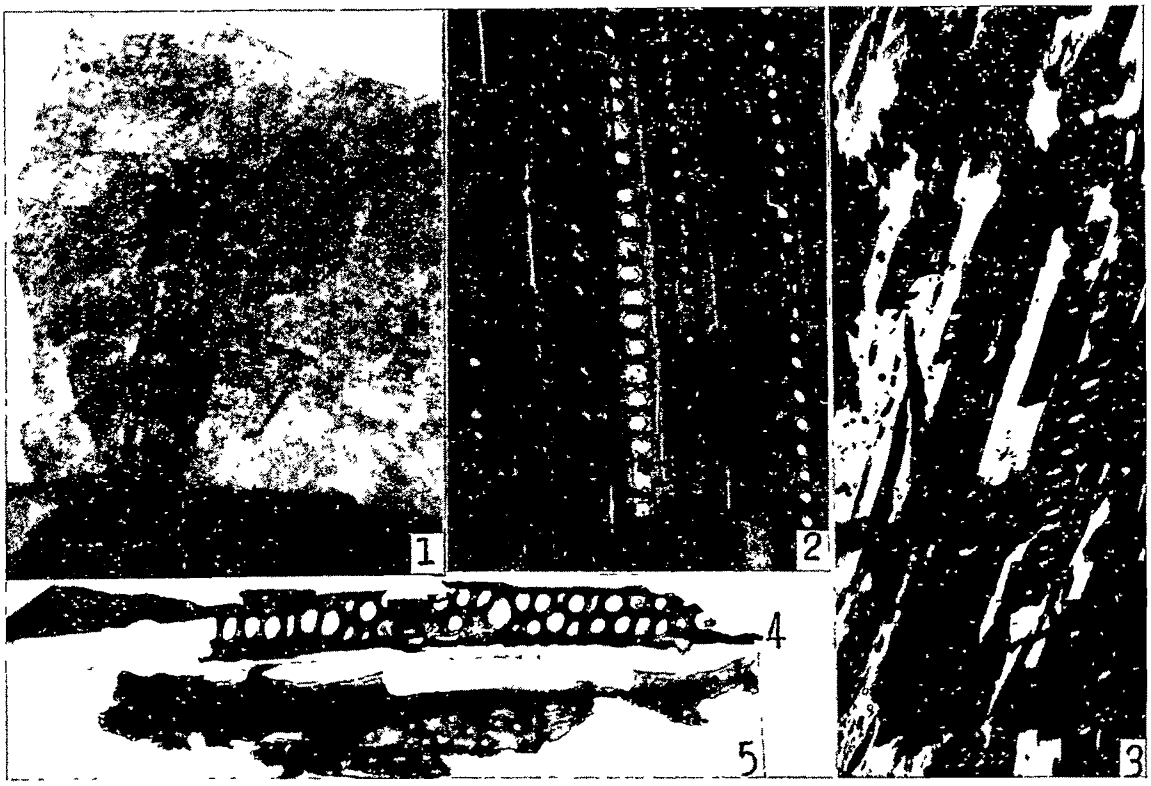

Fig. 1. Part of a shale showing a fusinized axis of *Vertebraria indica*, slightly less than natural size

Fig. 2. Maceration residue from one of the flat fusinized rectangular blocks of the axis shown in Fig. 1, showing tracheids of the secondary wood with uniseriate pitting. × 300

Fig. 3. Part of a cellulose-pull showing a number of tracheids with variously formed pit-closing membranes. × 300

Fig. 4. Maceration residue showing a tracheid with uni- to bi-seriate pitting of different shapes and sizes. × 300

Fig. 5. Maceration residue showing a tracheid with irregular pitting. × 300

All attempts to bring out the nature of the primary wood by getting suitable transverse sections of the fusain failed. Only the secondary wood could be profitably examined by preparing cellulose peel and maceration residues.

Since the structure of the secondary wood of *Vertebraria* has been excellently described by Walton and Wilson[1], only points of additional interest have been noted here. The tracheids vary considerably in breadth (15.5–40 μ), with one to three series of bordered pits on the radial walls. The pits are closely or slightly contiguous, rarely separated, and sometimes a few are abruptly isolated; they may be circular but are more often elliptical, and the size ranges from almost pinhole-like to quite large and well-formed pits (Figs. 2–3). In some tracheids there are regular closing membranes which may partially or wholly close the pit orifices (Fig. 3). The characteristic elliptical or slit-like pit orifices, when present, are due to the membranes closing in from either side of the pits (Fig. 2). The same tracheid may often bear uni- and regularly or irregularly bi-seriate pits of widely different shapes and sizes (Fig. 4). Sometimes the pits are all irregularly arranged (Fig. 5). Such features are often clearly visible and as such cannot be due to poor preservation. It appears that some of these tracheids are exhibiting transition stages between the scalariform and pitting[2]. The general impression is that the irregular organization of some of the tracheids is of primitive nature.

The entire thickly fusinized rectangular blocks yielded closely knit masses of tracheids often in association with small rays one to two cells high. The previous interpretation that "the rectangular areas represent the large medullary rays and the longitudinal and transverse grooves or ridges the secondary wood" only[1], therefore, needs careful re-examination.

It is expected that the examination of other similar specimens (now being sought) from the Sohagpur Coalfield may reveal the general nature of the anatomical organization, especially of the primary wood, in *Vertebraria*. This is obviously important for our knowledge of the *Glossopteris* flora.

I wish to thank Mr. S. K. Ghosh, geologist in the Sohagpur Coalfield, for the material.

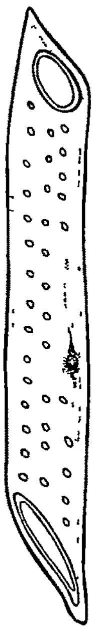
Presence of Nucleus and Cytoplasm in the Mature Vessel Elements and Fibre Tracheids in Japan Jute Plants

It is commonly held that the mature vessel elements of plants are non-living cells. In jute[1], the cell-wall of the vessel elements is lignified and has scalariform thickening and simple pits on the lateral walls Esau has stated "In the mature state, tracheids and vessel members are more or less elongated cells with lignified secondary walls and devoid of protoplasts" In a recent publication[2], she mentions (p 225) "After the secondary walls are fully formed and lignified the swollen parts of the primary wall break down (fig. 11 3,*F* and plate 25,*D*) and finally the protoplasts die and disappear". The course of events is interpreted by Shah[3] in the following way "The disappearance and loss of the protoplast usually synchronizes with the formation of perforation plates (Eames and MacDaniels, fig 49, Esau, figs 11–13)" Recently, I have described[4] how, during the course of development of primary vessel elements, "the protoplasts disappear after the deposition of the secondary thickening matter"

In a recent investigation of the stem of jute plants grown in East Bengal, nucleus and cytoplasm were found in the mature vessel elements and fibre tracheids of the secondary xylem (Figs 1–3) Nucleus and cytoplasm were not observed in the vessels of all the varieties of jute plants but only and rarely in the variety Japan of the species *Corchorus capsularis* The fibre tracheids in the secondary xylem with nucleus and cytoplasm are abundantly present in the varieties Fanduk and Japan of this species The nucleated vessel elements are considerably elongated cells having lignified walls, simple perforations and simple pits in the lateral walls The nucleus with a single nucleolus is prominent and lies embedded in a small amount of cytoplasm The cytoplasm is granular and vacuolated In the fibre tracheids both the nucleus and cytoplasm are very prominent The prominent cytoplasm in some fibre tracheids is found to extend more than half the length of each tracheid (Figs 2 and 3)



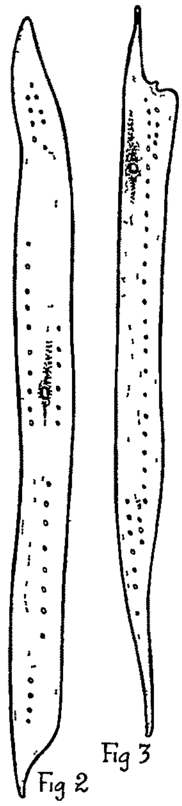


Fig 1 A vessel segment with a single perforation showing nucleus and cytoplasm × 550

Figs 2 and 3 Fibre tracheids of secondary xylem with prominent nucleus and cytoplasm × 550

This condition was first reported by Shah[3], who examined the macerated materials of the tendrils of *Vitis repens* growing in Surat I have also examined the macerated materials of the stems of jute plants

The finding of nucleus and cytoplasm in the mature vessel elements, as well as in the fibre tracheids, is contrary to the observations of Esau and of Eames and MacDaniels

Revision of Supposed Jurassic Angiosperms from New Zealand

In Arber[1], Laurent identified two angiosperms, *Artocarpidium arberi* Laurent and *Phyllites* sp, on a slab of matrix from a large collection from Waikato Heads, Arber[1] also identified *Cladophlebis australis* (Morris) in the same slab and suggested a Neocomian age for the whole collection In spite of intensive collecting at Waikato Heads, no further angiosperms have been found, and Edwards[2] doubted whether the slab came from Waikato Heads He concluded that the rest of the Waikato Heads flora is Upper Jurassic. Evidence is presented here in support of Edwards's suggestion that the slab did not come from Waikato Heads, and further that it came from Upper Cretaceous (about Maestrichtian) coal measures of Pakawau, South Island The age of the remaining plant fossils truly from Waikato Heads is not precisely known Dr C A Fleming (New Zealand Geological Survey) has told me that the underlying marine beds are probably Neocomian

The two angiosperms resemble specimens from Pakawau *Artocarpidium arberi* resembles *Fagus producta* Ettingshausen[3], and *Phyllites* sp resembles an undescribed species from Pakawau The fern-like plant on the slab identified as *Cladophlebis australis* by Arber[1] (Pl IV, Fig. 1, Pl XIV) and one cycad cannot be matched in other material from Waikato Heads It is really *Blechnum priscum* Ettingshausen[3], described from Pakawau, and not known from older rocks. In addition, I have identified a cycad on the slab as *Taeniopteris stipulata* Hector[4], a species founded on specimens from Pakawau and unknown from pre-Turonian beds in New Zealand *T. stipulata* was not recorded by Arber.

Moreover, the specimen of Arber's "*Cladophlebis australis*" (Arber[1], Pl. IV, Fig. 1) is also the original of a figure on an unpublished plate, prepared by Hector, in a series labelled "Pakawau" in his handwriting

The cause of the error may lie in the numbering of the specimens, specimens from Pakawau are registered with the New Zealand Geological Survey locality number 409 (collected by the Geological Survey in 1866), and those from Waikato Heads bear the number 410 (collected by the Geological Survey in 1868). Apparently, a slab from the Pakawau collection was wrongly numbered and placed in the Waikato Heads collection

The earliest New Zealand angiosperms known at present are those from beds in the Middle Clarence Valley, which on the evidence of plant microfossils are Turonian in age

A Seed-borne Nematode Infestation in Annual Asters

Aphelenchoides ritzema-bosi has a wide host-range but is most frequently recorded as a pest of chrysanthemums In this plant, infestations usually start at the base of the stem and work upwards in the direction of the flower head. In severe attacks, most of the leaf area is killed, and the flower head itself may become infested Chrysanthemums are normally propagated vegetatively, and hence seed-borne infestation is unlikely to occur. However, some hosts of *A ritzema-bosi* are grown from seed, and the object of this communication is to record seed-borne infestation in the annual aster (*Callistephus chinensis*).

In early May 1954, severe injury was noted on aster plants being grown in sterilized compost in seed boxes on a nursery in Suffolk. These plants were found to be heavily infested with *A. ritzema-bosi*, living mainly ectoparasitically in the leaf axils Fortunately a supply of the original seed was available for examination. 14 gm. of seed was placed in a Baermann funnel and more than three hundred nematodes were extracted Small pieces of leaf and sepal debris were present mixed with the seed, and nematodes emerged in large numbers from this debris and also from seed from which the debris had been removed It therefore seems probable that the species was living both ecto- and endo-parasitically in the flower head, and that a proportion of the nematodes was attached to or in close association with the seed coat. Identical symptoms were reproduced in the laboratory on aster plants raised from this seed in sterilized compost

Seed-borne infestation in the genus *Aphelenchoides* has not hitherto been recorded A full account of this occurrence and of the symptoms on the aster plants will be published elsewhere.

The Genetic Component of Language

R W. Thompson, in discussing the genetic component of language[1], complains that Darlington and Mather, in an introduction to genetics[2], "have simplified the issue" This is true, and one of the complications Mr Thompson introduces is highly appropriate But in my original paper I had considered it[3].

In this paper I tried to explain certain principles

(1) That the three threads by which continuity and change may be followed in language, namely, grammar, etymology and phonetics, are in a long-term sense independent.

(2) That only on the phonetic side do we expect or find a serious genetic component

(3) That the genetic preference of the group rath than the genetic capacity of the individual is wh determines phonetic evolution

Among the instances I gave of the working of these principles was the one quoted by Mr. Thompson, namely, the intrusion of the dental fricative along different lines, at different times and in different parts of the Spanish-speaking world, an instance which might be elaborated from the study of Latin American dialects.

Mr Thompson suggests that the theory of a genetic component of language was regarded as speculative by Darlington and Mather It is speculative in the sense that it is a beginning rather than an end of investigation It opens new ground for research in phonetics, linguistics, anatomy and psychology, and ultimately in the general understanding of human society. What we have to do is to apply non-genetic ideas and techniques in relation to the genetics of individuals and of populations

I may give an example of each.

(1) Mr Thompson agrees that "the speech organs of various races vary in shape". But he maintains that these variations could have no influence on the production of speech except on timbre Are we to suppose, then, that the defects of speech which may distinguish one child from his brothers and sisters never have any basis in the shapes of nerves, muscles or bones ? Or conversely, that the established genetic control of differences in tongue control has no effect on the ease of pronouncing various sounds ? I do not believe either of these corollaries of Mr. Thompson's view. But the anatomist and the speech therapist could test their truth, and their observations would help to solve our problem

(2) We have to discover just how the community, its classes and individuals, interact over long spaces of time in small and large, stable and changing, literate and illiterate societies We now understand enough of the genetics of these situations to relate them with the historical evidence[4].

Such is the speculation. But the principle of genetic determination in language itself is far from speculative Those who now object will be telling us soon enough that it is little more than a truism.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

ASSISTANT (Grade B), to organize and teach geology and geography to the standard of General B Sc (London)—The Clerk to the Governors, Luton and South Bedfordshire College of Further Education, 63-69 Guildford Street, Luton (January 29)

ASSISTANT LIBRARIAN (with at least A L A)—The Librarian, Chemical Society, Burlington House, Piccadilly, London, W 1 (January 29)

DEMONSTRATOR IN PHYSIOLOGY—The Secretary, London Hospital Medical College, Turner Street, London, E 1 (January 29)

ASSISTANT LECTURER IN THE DEPARTMENT OF CHEMISTRY at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W C 1 (January 31)

LECTURER (preferably with special qualifications in inorganic and analytical chemistry) IN CHEMISTRY, at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (South Africa, January 31)

LECTURER (with a good honours degree and some relevant experience, preferably including some research experience in the field of structures or soil mechanics) IN THE DEPARTMENT OF CIVIL ENGINEERING—The Registrar, The University, Bristol 8 (January 31)

SENIOR EXPERIMENTAL OFFICER (with a degree or equivalent qualification and laboratory administrative experience) IN THE BIOCHEMISTRY DEPARTMENT—The Secretary, Institute of Animal Physiology, Babraham, Cambs (January 31)

HENRY AND CHARLOTTE PAYNE RESEARCH FELLOW IN CYTOLOGY and/or CYTO-CHEMISTRY, with special reference to malignant cells—The Assistant Secretary, The Royal Society, Burlington House, Piccadilly, London, W 1 (February 1)

LECTURER or SENIOR LECTURER IN BIOLOGY—The Principal, The Training College, Ripon, Yorks (February 1)

SCIENTIFIC TECHNICAL OFFICER (preferably with H N C or similar qualifications in physics or chemistry), to assist in the preparation of intelligence reports, and to be responsible for internal scientific records, including preparation of monthly review of technical press —The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London S W 1, quoting TT/908 (February 2)

ANALYTICAL CHEMIST (with a degree in chemistry or at least H N C in chemistry) to work mainly on the analysis of plant material—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (February 5)

DIRECTOR (with wide research and administrative experience, and ability to co-ordinate research in the various divisions of the Institute, particularly applied research) OF THE CENTRAL ELECTRO-CHEMICAL RESEARCH INSTITUTE, Council of Scientific and Industrial Research (India), Karaikudi, South India—High Commission of India, Establishment Department, Aldwych, London, W C 2, quoting 4/85K (February 8)

LECTURER IN APPLIED PHARMACOLOGY AND THERAPEUTICS—The Dean St Thomas's Hospital Medical School, London, S E 1 (February 8)

PROFESSOR OF PHYSICS—The Registrar, The University, University Office, 46 North Bailey, Durham (February 12)

PHYSICIST (with a good honours degree in physics or similar professional qualifications, proved research ability and preferably some experience of stress analysis) in the Central Research Establishment, National Coal Board, Isleworth, Middlesex, to lead a group carrying out research on coal ploughing—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S W 1, quoting TT/906 (February 16)

UNIVERSITY DEMONSTRATOR IN PHYSICS—Dr F B Kipping, Chemical Laboratory, Pembroke Street, Cambridge (February 19)

ASSISTANT LECTURER OR DEMONSTRATOR IN PATHOLOGY—The Registrar, The University, Manchester 13 (February 26)

LECTURER/SENIOR LECTURER (preferably with interests and experience in clinical psychology) IN PSYCHOLOGY, at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (Australia, February 26)

SENIOR LECTURER IN EDUCATION at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (February 26)

SENIOR LECTURER (with special qualifications in chemical pathology) IN CHEMICAL PATHOLOGY—The Registrar, The University, Manchester (February 26)

CHAIR OF MATHEMATICS, CHAIR OF PHILOSOPHY AND PSYCHOLOGY, and a LECTURER IN MATHEMATICS, at Canberra University College, Canberra, A C T , Australia—The Secretary Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (Canberra, February 28)

CHAIR OF PHYSICS—The Registrar, The University, Hull (February 28)

CHAIR OF ANATOMY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (Australia, March 1)

I C I RESEARCH FELLOWS IN PHYSICS, CHEMISTRY, ENGINEERING, METALLURGY and PHARMACOLOGY, or any related subject, and LEVERHULME POSTGRADUATE FELLOWS (2) IN THE FACULTY OF SCIENCE—The Registrar, The University, Liverpool (March 1)

HEAD OF THE DEPARTMENT OF ENTOMOLOGY—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (March 31)

I C I RESEARCH FELLOWS IN BACTERIOLOGY, BIOCHEMISTRY, BIOMOLECULAR STRUCTURE, BOTANY (Plant Biochemistry and Biophysics), CHEMICAL ENGINEERING, CHEMISTRY, CHEMISTRY OF LEATHER MANUFACTURE, CHEMOTHERAPY, COLOUR CHEMISTRY and DYEING, ENGINEERING (Civil, Electrical or Mechanical), FUEL AND REFRACTORIES, GEOLOGY (including Geochemistry), METALLURGY, MINING (Selective Flotation and Geophysical Surveying), PHARMACOLOGY, PHYSICS, PHYSIOLOGY or TEXTILE INDUSTRIES (Protein Chemistry and Wool Textile Engineering)—The Registrar, The University, Leeds 2 (April 15)

LECTURER (with an honours degree in botany or agricultural botany, and preferably with postgraduate experience in plant physiology, ecology, genetics or virus pathology) IN THE DEPARTMENT OF AGRICULTURAL BOTANY—The Registrar, The University, Reading (April 15)

I C I RESEARCH FELLOWS IN PHYSICS, CHEMISTRY, BIOCHEMISTRY, ENGINEERING, METALLURGY, PHARMACOLOGY, CHEMOTHERAPY or related subjects—The Secretary General of the Faculties, The Old Schools, Cambridge (April 30)

AGRONOMIST, Scientific Officer or Senior Scientific Officer grade (with at least a second-class honours degree, and not less than two years appropriate postgraduate experience, preferably including acquaintance with tropical tree crops and up-to-date knowledge of the statistical analysis of field experimental results), at the West African Cocoa Research Institute, to assist in laying down field experiments on various methods of cultivating cocoa—Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S W 1, quoting BCD 197/200/05

CHEMIST, Senior Scientific Assistant (with a good honours degree or equivalent qualification, experience in industry, and ability to prepare correspondence and reports), at the Central Laboratory, Chiswick, to be responsible for a section concerned with a wide variety of analytical and investigational work—The Staff Officer (F/EV 507), London Transport, 55 Broadway, London, S W 1

EXPERIMENTAL OFFICERS (preferably with a pass degree), and ASSISTANT EXPERIMENTAL OFFICERS (with at least H S C (science) or equivalent), to assist in the preparation of experimental equipment and in the carrying out of nuclear physics experiments—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 349/WGE/34

EXPERIMENTAL OFFICER (with a degree or equivalent qualifications) IN THE NUTRITION DEPARTMENT, to assist in biochemical research involving chromatography and electrophoresis—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting 55/2

FORESTAL LAND, TIMBER AND RAILWAYS CO, LTD, RESEARCH FELLOW (with at least a good honours degree in chemistry, and preferably some research experience, and particular interest in applying fundamental physical chemistry and physical methods of organic chemistry to problems of industrial importance), at the Central Research Laboratory of the Department of Scientific and Industrial Research, Teddington, for research which will be directed to investigating the function of tannins in preventing corrosion of metals—Chief Research Chemist, Forestal Central Laboratory, Harpenden, Herts

HEAD OF THE DEPARTMENT OF CHEMISTRY AND BIOLOGY, and HEAD OF THE DEPARTMENT OF ENGINEERING, at the College of Technology and Commerce, Cardiff—The Director of Education, City Hall, Cardiff

LECTURERS (2) (with an engineering or science degree, lecturing experience, and a specialist knowledge of either electrical engineering or electronics, or survey mechanism) at the R E M E Training Centre, Arborfield—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1, quoting D 679/54A

MASTER to teach MATHEMATICS up to University Scholarship standard—The Headmaster, Highgate School, London, N 6

MATHEMATICIANS and THEORETICAL PHYSICISTS, to investigate a range of problems in classical and nuclear physics—The Deputy Director, Atomic Weapons Research Establishment, Aldermaston, Berkshire

NUCLEAR PHYSICISTS, Senior Scientific Officer or Scientific Officer grade (with a first- or second-class honours degree in physics or equivalent qualification, and in the case of the S S O posts some years postgraduate research experience in nuclear physics), to work with a 6 MeV Van de Graaff generator and other accelerators—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 348/WGE/34

PRINCIPAL (with experience of teaching, administrative ability and a knowledge of agricultural practice) OF THE INSTITUTE OF AGRICULTURE AND HORTICULTURE, "Oaklands", St Albans—County Education Officer, County Hall, Hertford

SENIOR RESEARCH ASSISTANT (with a good honours degree in engineering, practical experience and/or research training) IN THE DEPARTMENT OF CIVIL AND MECHANICAL ENGINEERING—The Registrar, The University, Nottingham

Philips Diffraction Apparatus Type 11704

Send for fully descriptive literature

PHILIPS

X-ray Diffraction Unit

. . . high efficiency at low cost

This 'always ready to switch on' X-ray Diffraction Unit, Type 11704, has many uses and many users. Employing PHILIPS 'sealed-off' tubes with mica-beryllium windows, up to four cameras can be used simultaneously. Simplicity of operation and small dimensions are outstanding features. The price is modest in the extreme.

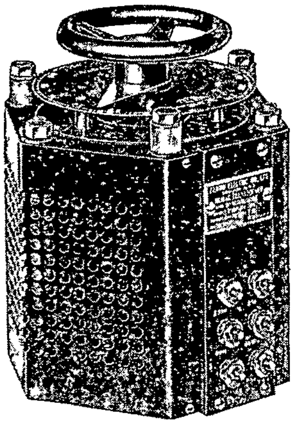
***ZENITH *VARIACS with *DURATRAK**
* REGD. TRADE-MARKS



All VARIAC-DURATRAK Variable Voltage Transformers have a brush track treated in accordance with British Patent No. 693406, which produces a coating of precious metal alloy on the brush track surface, eliminating the possibility of deterioration due to oxidization, and reducing contact resistance.

VARIACS with DURATRAK have longer life, increased overload capacity and maximum economy in maintenance.

LECTURES AND COURSES

UNIVERSITY OF BRISTOL

DIPLOMA IN HORTICULTURAL SCIENCE
DIPLOMA IN PLANT PATHOLOGY AND PROTECTION

Courses for the above postgraduate qualifications will commence on September 16 1955 They extend over a full university session of three terms ending in the following June or July Conducted in part at the Long Ashton Research Station, they are intended primarily for those with good honours degrees in science who seek careers in horticultural research, at home or abroad

Early application should be made to the undersigned, from whom full particulars may be obtained

H C BUTTERFIELD,
Registrar and Secretary

UNIVERSITY OF LONDON

DEPARTMENT OF EXTRA-MURAL STUDIES

University Extension Residential Courses in (1) Trends in Physics Research and Teaching, (2) Meteorology Both courses take place April 14 to 20, 1955 Two separate residential courses of one week's duration at Imperial College of Science and Technology, London, for graduates and those with similar experience Lecturers The Professors and Lecturers of the Departments of Physics and Meteorology at the Imperial College of Science and Technology

Further information and application forms may be obtained from the Deputy Director (Ex Nat), Department of Extra-Mural Studies, University of London, Senate House, W C 1

UNIVERSITY OF LONDON

A lecture on "Recent Changes in Spanish Economy" will be given by Professor L P Pardo (School of Advanced Commercial Studies, Barcelona) at 5 30 p m on January 31 at University of London Senate House W C 1

Admission free, without ticket

JAMES HENDERSON,
Academic Registrar

UNIVERSITY COLLEGE LONDON, GOWER Street, W C 1 Applications for admission to the B Sc (Special) Course in Zoology, commencing in October, 1955, must reach the Registrar not later than Friday, February 25, 1955 Selected applicants (who will be notified individually) will be required to take a written and practical test in the Department of Zoology on Friday March 25, 1955, from 10 a m to 5 p m The final selection of candidates for admission will, with certain exceptions, be made from those successful in this test

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 *to* 64 *inclusive, or a woman aged* 18 *to* 59 *inclusive unless he or she, or the employment is excepted from the provisions of the Notification of Vacancies Order,* 1952

COMMONWEALTH of AUSTRALIA

DEPARTMENT OF SUPPLY
AERONAUTICAL RESEARCH LABORATORIES
FISHERMEN'S BEND, VICTORIA

Applications are invited for a temporary position of Senior Experimental Officer at the above laboratories Salary £A 1 352 to £A 1 442 per annum Duties Responsible for initiating, planning and conducting experimental projects related to the strength of aircraft materials and components and for developing and improving experimental methods and equipment Qualifications A degree or diploma in engineering or science, or equivalent with passes in pure and applied mathematics I, physics I metallurgy I and strength of materials A sound knowledge of theoretical stress analysis and several years' experience in an engineering laboratory essential Engineering drawing and design experience an advantage Whilst the position is a temporary one the tenure of employment is not limited Under specified conditions, first-class boat fare (if first-class berth available) for the appointee and dependants (wife and dependent children) will be paid by the Commonwealth

Application forms obtainable from Senior Representative (AP 25) Department of Supply Australia House, Strand, London, W C 2, with whom applications should be lodged by February 5, 1955

SOUTH AFRICAN COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

METALLURGIST RESEARCH OFFICER

Applications are invited for a post as Research Officer in the Mechanical Engineering Research Laboratory of the C S I R, Pretoria, South Africa The salary scale associated with this post is £780 by £48 to £1 020 per annum In addition, a cost-of-living allowance of £234 per annum is payable to married male officers Starting salary according to qualifications and experience Generous leave privileges and five-day week Candidates must be in possession of at least an honours degree in metallurgy or metallurgical engineering, or equivalent qualification The successful candidate will do research work in the field of ferrous and non-ferrous physical metallurgy The successful candidate will be required to furnish a medical certificate of good health and to become a member of the University Institutions Provident Fund The Council will bear the transportation costs of the appointee and his family from his place of residence to Pretoria Further information and application forms are obtainable from the South African Scientific Liaison Officer, Africa House, Kingsway, London W C 2

Applications, giving full details of age, marital status, qualifications, experience and the names of referees, must reach the Secretary/Treasurer, C S I R P O Box 395 Pretoria, South Africa, before March 15 1955 A copy of the application must be sent to the South African Liaison Officer in London

---

CHELSEA POLYTECHNIC

MANRESA ROAD, S W 3
HEAD OF DEPARTMENT OF GEOLOGY

The Governors invite applications for the post of Head of the Department of Geology, which becomes vacant through the retirement of Dr W F Fleet Candidates should possess high qualifications in geology, and have had experience in both teaching and research Salary scale, Grade II (men, £1 065 by £25 to £1 215, women £852 by £20 to £972) plus London allowance of £36 or £48 according to age Duties to commence September 1, 1955

Further particulars and form of application may be obtained by sending stamped, addressed foolscap envelope to the undersigned, to whom applications must be returned not later than February 28, 1955

N M H LIGHTFOOT, M A, F R S E
Principal

ST THOMAS'S HOSPITAL MEDICAL SCHOOL

A Lecturer in Applied Pharmacology and Therapeutics is required by the Department of Therapeutics Salary will be according to the scale for a Junior Lecturer or Lecturer according to experience, with family allowance

Applications giving full particulars and the names of two referees, should be sent before February 8 to the Dean, St Thomas's Hospital Medical School, London, S E 1

CHESTER BEATTY RESEARCH INSTITUTE (Institute of Cancer Research Royal Cancer Hospital) Two Technicians required (a) Biochemical technician preferably with experience of manometric techniques or in the isolation of natural products, (b) Technician for physical chemistry laboratory, for work particularly concerned with spectroscopic techniques, experience in this field would be an advantage Both posts are permanent and superannuable, and the salary will be according to age experience and qualifications—Applications, marked respectively "Biochemistry" and "Spectroscopy" should be addressed to the Chester Beatty Research Institute, Fulham Road London S W 3

LONDON TRANSPORT INVITE APPLICATIONS for experienced chemists for Senior Scientific Assistant post Central Laboratory Chiswick, with responsibility for section concerned with wide variety of analytical and investigational work, dealing with detergents, cleaning materials, effluents water treatment, weed killing disinfectants, insecticides, adhesives fire extinguishing materials textiles and leathercloths, preparation and revision of material specifications etc Good honours degree or equivalent qualification experience in industry ability to prepare correspondence and reports Salary range £980 by £25/£50 to £1,180 Commencing salary according to qualifications and experience, medical exam, contributory superannuation scheme after probation—Applications to Staff Officer (F/EV 507), London Transport, 55 Broadway, S W 1 For acknowledgement enclose addressed envelope

---

GOVERNMENT OF NORTHERN IRELAND

INDUSTRIAL USE OF ATOMIC ENERGY
APPOINTMENT OF AN ENGINEER FOR SPECIAL TRAINING

Applications are invited from Engineers with suitable qualifications for an appointment under the Ministry of Commerce for Northern Ireland in connection with developments in the use of nuclear energy in the generation of electricity The appointment will be conditional upon the acceptance of the selected candidate by the Atomic Energy Authority for a course of instruction to which he will be presented by the Ministry, and continued employment will be dependent on satisfactory completion of that course The appointment will be on a contract of service for a period of six years in the first instance, during which the officer may be required to serve on loan, with any statutory body in Great Britain or Northern Ireland designated by the Ministry The contract of service may be extended, or may be terminated by agreement, to enable the Engineer to take up a permanent appointment in the service of the Electricity Board for Northern Ireland The Engineer will be expected, when required, to take part in the design and construction of an electric power station to operate on nuclear energy in Northern Ireland and to take charge of its operation when completed, and he may accordingly expect to be offered a permanent appointment at that stage at latest Candidates should hold an honours degree in engineering or physics of a recognized university, and if the degree is not in physics other evidence of an adequate knowledge of this subject should be furnished Corporate membership of at least one of the institutions of civil, mechanical, or electrical engineers or evidence of an early expectation of obtaining it, will also be required Pay on appointment will be at the rate of £1,000 a year, and, on completion of training, will be at the rate of £1,200 a year, which may be increased from time to time up to a maximum of £1 500 a year, according to the nature of the work Special allowances for accommodation, etc, while in attendance at the course of instruction and while serving on loan will be considered if the circumstances require

Application forms may be obtained from the Director of Establishments Ministry of Finance, Stormont, Belfast, and must be returned, duly completed with copies of two recent testimonials so as to reach him not later than February 8, 1955

COMMONWEALTH of AUSTRALIA

DEPARTMENT OF SUPPLY
AERONAUTICAL RESEARCH LABORATORIES
FISHERMEN'S BEND VICTORIA
SENIOR SCIENTIFIC OFFICER
(Temporary position)

Salary £A 1 502 to £A 1 688 per annum Duties Responsible for the investigation of instrumentation schemes in the field of aeronautical research, for detailed investigation of resultant problems and the subsequent development of necessary apparatus Qualifications University degree of high standard in electrical engineering or physics, with mathematics or mathematical physics to final honours standard or equivalent qualifications and several years' experience of research in the above or an allied field A knowledge of analogue to digital conversion systems or servo-mechanisms and automatic control systems would be an advantage Under specified conditions first-class boat fare (if first-class berth available) for the appointee and dependants (wife and dependent children) will be paid by the Commonwealth

Application forms obtainable from Senior Representative (AP 24) Department of Supply Australia House, Strand London, W C 2 with whom applications should be lodged by February 5, 1955

HERTFORDSHIRE COUNTY COUNCIL

HATFIELD TECHNICAL COLLEGE
Principal W A J Chapman M Sc (Eng), Ph D, M I Mech E, M I P E

Required to commence duties April 1, 1955, or as soon as possible thereafter, Laboratory Steward with recognized qualifications and with special interest in physics Some experience in a teaching laboratory is desirable Salary on N J C scales for local authorities' miscellaneous classes of officers, Grade III and IV, £395 to £520 per annum

Applications, giving qualifications and experience and names of two referees, to the Registrar, Hatfield Technical College, Roe Green, Hatfield, Herts

MILK MARKETING BOARD FOR NORTHERN IRELAND

Applications are invited from suitably qualied persons for the undernoted posts in the Milk larketing Board for Northern Ireland The osts will be permanent subject to a probationary od of two years Candidates must be of ritish nationality Preference will be given to ersons who served in H M Forces during the 914-18 or 1939-45 wars General Manager pplicants must have had considerable experience a senior administrative capacity of the probems undertaken in a large-scale marketing organation preferably in connection with milk The ccessful applicant will be responsible, subject the directions of the Board for the general ontrol of all the Board's activities Salary will e on the scale of £2 000 to £2,400 per annum ccountant and Finance Officer The applicant ust be a member of an Institute of Chartered ccountants the Society of Incorporated Accoun ants or the Association of Chartered and Cororated Accountants Preference will be given to ersons with experience of costing commercial rocesses, and who have experience of the operaon of mechanized accounting Salary will be on e scale of £1,200 to £1 500 per annum Adinistrative Officer The successful applicant will responsible to the General Manager for the dministrative and clerical work of the Board pplicants must have had considerable experience similar capacity preferably in connection the milk industry Salary will be on the le of £1 200 to £1 500 per annum Techal Officer Applicants must hold qualifications dairy technique and in the manufacture of milk oducts It would be to the applicant's adntage if he has had experience in organising ilk transport on a large scale Salary will on the scale of £1 200 to £1,500 per annum or any of the above posts the Board may pay commencing salary above the minimum to speally qualified persons

Applications must be made on the prescribed rm copies of which may be obtained from the cting Secretary Milk Marketing Board for orthern Ireland, Castlehill Road, Belfast, orthern Ireland The latest date for the receipt applications will be January 31 1955

AUSTRALIAN NATIONAL UNIVERSITY

JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

Applications are invited from organic chemists r the position of Research Fellow who will a research assistant to the Professor of Medil Chemistry Candidates should have a Ph D gree (or equivalent research experience) The ccessful applicant will undertake full-time rearch in laboratories which are well equipped r the purpose on the synthesis of new heteroclic compounds, in particular pteridines, pyriidines and purines The appointment will for one, two or three years in the first stance and if the appointment is made for period longer than one year, the successful plicant will later be required to transfer to anberra with the Department The Department s laboratories are at present located at 183, uston Road London N W 1 The salary range £1,100 to £1 650 and superannuation will be vided on the F S S U pattern

Further particulars and information as to the ethod of application may be obtained from e Secretary Association of Universities of the itish Commonwealth 5 Gordon Square, Lonn W C 1 with whom applications close on bruary 28 1955

CENTRAL RESEARCH ESTABLISHMENT ational Coal Board (at Isleworth Middlesex) ich is concerned with mining problems invite plications for the superannuable appointment a Physicist to lead a group carrying out rerch on coal ploughing The work will be ncerned initially with a study of the internal ess distribution and breakage pattern induced a brittle solid containing internal weaknesses the application of a localized continuous or pulsive force Candidates should have a good nours degree in physics or similar professional alifications proved research ability and preferly some experience of stress analysis Appointent will be as Scientist Grade I (scale £1 150 by 0 to £1 350 thence by range to £1 550 male us London location allowance of £82 minimum g to £100 at maximum) —Write giving full rticulars (in chronological order) of age educan qualifications and experience (with dates) National Coal Board Establishments (Personl) Hobart House Grosvenor Place London, W 1 marking envelope TT/906 Original testionials should not be forwarded Closing date bruary 16, 1955

ROWETT RESEARCH INSTITUTE

Applications are invited for the following posts for research on the nature of host parasite relationships (1) Bacteriologist particularly to study the role of antibodies in immunity (2) Pathologist or Histologist, who would also be responsible for problems concerned with histology and morbid anatomy Both posts will be in the Scientific Officer or Senior Scientific Officer grades with initial placing according to age qualifications, and experience, and superannuation under F S S U Salary scales (men) Scientific Officer, £445 to £815, plus supplement £22 10s to £30, Senior Scientific Officer, £935 to £1 090 plus supplement £35 The rates for women are slightly lower

Applications, stating date of birth with particulars of education qualifications and experience together with the names of three referees should be sent to the Secretary, Rowett Research Institute Bucksburn, Aberdeenshire, as soon as possible

NATIONAL VEGETABLE RESEARCH STATION

WELLESBOURNE, WARWICK

ANALYTICAL CHEMIST

Applications are invited for the above post, to work mainly on the analysis of plant material Candidates should have a degree in chemistry or at least the higher national certificate in chemistry Salary in the Assistant Experimental Officer grade £288 per annum at 18 rising to £640 per annum for men or £540 per annum for women Starting salary according to age Superannuation scheme

Applications (four copies), with names and addresses of three referees to the Secretary by February 5, 1955

UNIVERSITY OF QUEENSLAND

AUSTRALIA

Applications are invited for two posts in the Department of Veterinary Clinical Studies (i) Chief Lecturer or Senior Lecturer in Veterinary Clinical Medicine, (ii) Senior Lecturer or Lecturer (Grade I) in Veterinary Clinical Medicine The successful applicant for the senior post will be expected to be responsible for organizing teaching and research in this subject The salary ranges are £A 1 800 to £A 2 050 per annum for Chief Lecturer £A 1,500 to £A 1 750 per annum for Senior Lecturer and £A 1,275 to £A 1,450 per annum for Lecturer (Grade I)

Further particulars are obtainable from the Secretary, Association of Universities of the British Commonwealth 5 Gordon Square London W C 1 Applications close in Australia and London on February 19 1955

NOTTINGHAM AND DISTRICT TECHNICAL COLLEGE

Principal H Baker Ph D, A M I C E, A M I Mech E

Applications are invited for the post of Assistant Lecturer, Grade B in Physics Applicants should possess an honours degree in physics and be able to teach the subject up to B Sc degree level and mathematics up to advanced level Preference will be given to candidates able to take one branch of physics up to B Sc (special) standard Salary will be in accordance with the Burnham Scale for Technical Teachers which for Assistants Grade B is at present £525 to £820 (men) £475 to £655 (women together with degree and training allowances in appropriate cases

Further particulars and forms of application may be obtained from the Registrar Nottingham and District Technical College Shakespeare Street Nottingham to whom they should be returned not later than January 31 1955

F STEPHENSON,
Clerk to the Joint Education Committee

UNIVERSITY OF CAMBRIDGE

Applications are invited for a University Demonstrator in Physics The Demonstrator will hold office from October 1 1955 and applications close on Saturday, February 19 1955

Details of duties salary etc may be obtained from Dr F B Kipping Chemical Laboratory, Pembroke Street Cambridge

---

SENIOR BIOCHEMIST REQUIRED FOR three-year appointment in mental deficiency research at Fountain Hospital Tooting with additional technical facilities at Galton Laboratory W C 1 in the first instance Whitley Council conditions of service Salary £835 rising to £1 080 plus £40 London weighting —Applications with qualifications and experience to Group Secretary, Fountain Hospital, London, S W 17

WEST AFRICAN COCOA RESEARCH INSTITUTE

A vacancy exists in the Institute for an Agronomist (Scientific Officer or Senior Scientific Officer) to assist in laying down field experiments on various methods of cultivating cocoa Qualifications Candidates must possess at least a second-class honours degree with not less than two years' appropriate postgraduate experience preferably including acquaintance with tropical tree crops and up-to-date knowledge of the statistical analysis of field experimental results Terms of Appointment On probation on terms applicable to the Research Branch of Her Majesty's Oversea Civil Service Emoluments These consist of salary and overseas research allowance in the following ranges Scientific Officer, £860 to £1,057 a year, Senior Scientific Officer, £1 162 to £1,472 a year Point of entry into the basic salary scales depends upon age, qualifications and experience For appointment to the Senior grade suitably qualified candidates must have had at least three years' approved postgraduate experience and be not less than 26 years of age Outfit allowance of £60 on first appointment Contributory superannuation scheme Government quarters when available at rental of 10 per cent of basic salary (maximum £150 a year) Free passages for officer wife and children under 13 years of age on appointment and leave Taxation at local rates

Apply with brief particulars, to the Director of Recruitment, Colonial Office, Sanctuary Buildings Great Smith Street, London, S W 1, quoting reference BCD 197/200/05

SOUTH PACIFIC COMMISSION

PLANT AND ANIMAL QUARANTINE OFFICER

Applications are invited for the post of Plant and Animal Quarantine Officer with the South Pacific Commission The successful applicant will be appointed for a period from two to three years, and will be stationed at the Commission's headquarters in Noumea New Caledonia The Plant and Animal Quarantine Officer is required to carry out investigations, etc, relating to the control of plant and animal pests diseases, and weeds in the South Pacific including supervision of a rhinoceros beetle research programme, operation of an information centre and reporting service and improvement of control and protective measures Applicants should have a university degree with good scientific qualifications and mature experience in the field of plant or animal pests or diseases and their control and prevention including quarantine measures Fluency in English and French is very desirable Commencing salary will be determined according to qualifications and experience but will be not less than £Stg 1 600 plus a post allowance of £Stg 540 (single) or £Stg 901 (married)

Further information obtainable from the Secretary-General South Pacific Commission, Noumea New Caledonia to whom applications supported by a detailed curriculum-vitae should be sent by March 31 1955

VICTORIA UNIVERSITY COLLEGE

WELLINGTON NEW ZEALAND

Applications are invited for a Senior Lectureship in Physical Chemistry The salary will be £1 092 8s per annum rising by annual increments of £50 to £1 292 8s per annum The initial salary will be determined according to the qualifications and experience of the appointee Approved fares to Wellington will be allowed for the appointee, his wife and his children The successful applicant would be expected to take up his duties on May 1, 1955 or at such other date as may be agreed upon

Further particulars and information as to the method of application may be obtained from the Secretary Association of Universities of the British Commonwealth 5 Gordon Square, London W C 1 The closing date for the receipt of applications in New Zealand and London, is March 1 1955

HOMERTON COLLEGE

CAMBRIDGE

Applications are invited for September, 1955, or earlier for the post of Senior Lecturer in Science, who will be required to undertake direction of a Supplementary Science Course Candidates should have good qualifications and recent teaching experience, in either physics or chemistry The post offers scope for scientists interested in planning and carrying through a new course for prospective teachers of general science in secondary schools

Application forms and further details are available from the Secretary to whom applications should be sent before February 10

COMMONWEALTH of AUSTRALIA

DEPARTMENT OF SUPPLY
DEFENCE STANDARDS LABORATORIES
MARIBYRNONG, VICTORIA

Applications are invited for a temporary position of Principal Scientific Officer at the above laboratories Salary £A 1,688 to £A 1,874 per annum Duties To direct research and development in physical optics and optical instrument technology Qualifications University degree of high standard in physics, together with extensive relevant research experience, and proved capacity to initiate and conduct research in these fields Whilst the position is a temporary one, the tenure of employment is not limited However, the successful applicant may choose to enter into an agreement for a three- to five-year contract of employment in Australia In this case, the Commonwealth will bear return fare, together with cost of removing each way the appointees' furniture and effects up to a maximum cost of £A 500 Under specified conditions, first-class boat fare (if first-class berth available) for the appointee and dependants (wife and dependent children) will be paid by the Commonwealth

Application forms obtainable from Senior Representative (AP 26), Department of Supply, Australia House Strand London, W C 2, with whom applications should be lodged by February 5, 1955

UNIVERSITY OF WALES

Applications are invited for two I C I Research Fellowships in physics, chemistry, pharmacology metallurgy, engineering, geology or agricultural science, or in a subject allied to these The Fellowships, normally tenable for three years from October 1, 1955, will be held within the University of Wales One Fellowship shall be tenable at the University College of Swansea the other may be held at any of the constituent Colleges of the University or at the Welsh National School of Medicine The salary will depend upon qualifications and experience, but will be within the range of £600 to £900, together with F S S U benefits and family allowances

Further particulars may be obtained from the Registrar of the University of Wales University Registry, Cathays Park, Cardiff, by whom applications must be received not later than March 31, 1955

UNIVERSITY OF MANCHESTER

TURNER AND NEWALL RESEARCH FELLOWSHIPS

Applications are invited for the above Research Fellowships, founded by Messrs Turner and Newall, Ltd , tenable in the University and available for research in engineering inorganic chemistry physics and allied subjects The value of the Fellowships will be within the range of £600 to £900 per annum according to qualifications and experience

Regulations governing the award of the Fellowships may be obtained from the Registrar The University, Manchester, 13 to whom applications should be sent not later than April 30, 1955

AIR MINISTRY REQUIRES SCIENTIFIC Officers for Operational Research in or near London under direction of Scientific Adviser to Air Ministry Qualifications First- or second-class honours degree or equivalent in mathematics, physics or economics Salary (London) within range £492 10s to £885 Provincial rates and rates for women somewhat lower Posts unestablished with possibilities of establishment through Civil Service Commission for successful candidates whilst remaining under age 31 —Application forms, quoting A 384/54A, from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1

DEPARTMENT OF SCIENTIFIC AND INdustrial Research require an Assistant Experimental Officer (unestablished) at the Food Investigation's Torry Research Station Aberdeen, for work on fish muscle proteins, mainly from the physico-chemical and biochemical viewpoints Candidates must have G C E advanced level in chemistry and physics or equivalent over 22 a pass degree, with chemistry as main subject and physics subsidiary or equivalent will generally be expected An interest in biology or biochemistry an advantage Inclusive annual remuneration for a 45½-hour week within the range £297 (at age 18) to £659 (men) £297 (at age 18) to £556 (women) Prospects of establishment for candidates under 28 —Application forms from Ministry of Labour and National Service Technical and Scientific Register (K) Almack House 26 King Street London, S W 1 quoting F 840/54A Closing date February 12, 1955

MAKERERE COLLEGE

UNIVERSITY COLLEGE OF EAST AFRICA

Applications are invited for Assistant Lectureship in Department of Chemistry Salary scale £816 by £36 to £924 per annum Temporary cost-of-living allowance 10 per cent of basic salary F S S U Child allowance £50 per annum per child (maximum £150 per annum) Rent, according to quarters provided, £45 to £85 per annum, including basic furniture Free passages for member of staff and family (up to four adult passages) on appointment, termination and leave (three months every two years)

Applications (six copies), naming three referees, and detailing qualifications and experience, to be received by January 31, 1955, by Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W C 1, from whom further particulars may be obtained

---

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS

Applications are invited for the post of Head of the Department of Entomology The appointment will be in the Senior Principal Scientific Officer grade (£1 600 by £75(3) by £25 to £1,850) Superannuation F S S U The successful applicant will be required to take up duty on October 1, 1955

Applications, together with names of two persons to whom reference may be made, should reach the Secretary by March 31, 1955

GUY'S HOSPITAL

LONDON, S E 1

Applications are invited for the post of Technician (Senior Grade) in the Physics Workshop of the Radiotherapy Department Previous experience in hospital physics workshop desirable

Applications, giving details of age, qualifications and previous experience, together with the names of two referees, should be sent to the Superintendent, Guy's Hospital, on or before January 31, 1955

UNIVERSITY OF CAMBRIDGE

I C I FELLOWSHIPS

Applications are invited for Research Fellowships, value within the range £600 to £900 a year, founded by Imperial Chemical Industries, Ltd tenable in the University and available for research in physics, chemistry, biochemistry, engineering, metallurgy, pharmacology, chemotherapy or related subjects Applications must be received not later than April 30, 1955

Regulations governing the award of the Fellowships may be obtained from the Secretary-General of the Faculties, The Old Schools, Cambridge, to whom all applications should be addressed

---

UNITED SHEFFIELD HOSPITALS

ROYAL INFIRMARY UNIT

Applications are invited from university graduates holding the B Sc (Bact) or B Sc General with bacteriology as one of the subjects for the post of Non-medical Bacteriologist (basic grade) in the Department of Bacteriology Salary during probationary period £410 to £510 per annum, according to qualifications, and after probationary period £585 by £30 to £765 per annum

Applications with the names of three referees, should be addressed to the Superintendent, Royal Infirmary, Sheffield 6

LONDON COUNTY COUNCIL

(1) Assistant Superintendent (2) Collector of Botanical Specimens required for Nature Study Scheme for Schools based at Avery Hill, S E 9 Rates £306 to £701 a year (appointment above minimum as appropriate) and 135s to 154s 6d a week respectively

Application forms with full details, from Education Officer (EO/Estab 2/B), The County Hall, London S E 1, must be returned by February 4 (1687)

RESEARCH ASSISTANT (MAN) WANTED as soon as possible for university work on structure of alloys of high melting point The position offers good opportunities for learning high temperature methods The work is arranged so that the man appointed qualifies as an advanced student for the Oxford D Phil degree Requirements First-class honours degree in metallurgy physics or chemistry Salary according to qualifications Applications from overseas cannot be considered and men with second-class honours should not apply unless they have research experience —Applications to Dr W Hume-Rothery, O B E F R S Inorganic Chemistry Laboratory, South Parks Road Oxford

---

ROYAL COLLEGE OF VETERINARY SURGEONS

APPOINTMENT OF EXAMINERS
DIPLOMA IN VETERINARY STATE MEDICINE

Applications are invited for Examiners to form a panel as under for an examination to be held in Edinburgh in June next Group I Principles of bacteriology and immunity as applied t Veterinary State Medicine (Two) Group I (a) Veterinary hygiene and preventive medicine (One) (b) Food hygiene, including meat an milk inspection and control (One)

Candidates for appointment must make application not later than February 28 1955, and submi statements of their qualifications and copies o any testimonials they may desire to present Fo further particulars please apply to the undersigned

W G R OATES
Registrar

UNIVERSITY OF MANCHESTER

Applications are invited for posts of Lecture in Engineering Civil engineering candidates should have particular interest in elasticity, hydraulics, or surveying , mechanical engineering candidates should have particular interest in hea transfer, fluid mechanics thermodynamics and/o applied mechanics The present salary scale rises to £1,100 per annum, but is under review Initial salary according to qualifications and experience Membership of F S S U and childre allowance scheme Applications will also be c sidered from engineers who would be interest in a temporary appointment of two or m years

Applications should be sent not later tha February 15, 1955, to the Registrar, The Unive sity Manchester, 13, from whom further parti culars and forms of application may be obtained

---

LONDON COUNTY COUNCIL

London School of Printing and Graphic Arts Graduate in Physics or Chemistry, to teach fundamental principles of science and their applicatio to printing photography, paper and ink-making Industrial and/or teaching experience desirable Facilities for research Burnham salary sca grade B, £561 by £25 to £868, plus graduate an training additions (maximum £90 and £54) a applicable Starting salary according to age qualifications and experience

Application forms from the Principal at Bac Hill E C 1 Closing date February 4 (33)

LONDON COUNTY COUNCIL

London School of Printing and Graphic Arts Head of Department of Science and General Education , candidates must be graduates (preferabl science) with administrative experience Th Department covers applied science for whole-tim and part-time students , paper and printing in technology , English, arithmetic and social studie for apprentices Opportunities for research Salary £1,065 by £25 to £1,215, plus Londo allowance (maximum £48)

Application forms from the Principal, at Bac Hill, E C 1 Closing date February 4 (34)

COLLEGE OF ARTS AND SCIENC

BAGHDAD IRAQ

Applications are invited for the post of Reade and three posts of Senior Lecturer or Lecture in Physics Term of appointment to commenc not later than October 1 1955 Salaries are i the range ID 1,400 to ID 2,400 (1 ID =£1), tc gether with a cost-of-living bonus of at leas ID 120 and certain other allowances Passage are paid at beginning and end of contrac Annual summer leave is permitted Persons ap pointed are required to carry on research an to teach candidates for B Sc degree Teaching in English Climate and conditions are suitabl for British families

For further information apply to the unde signed

A A DURI
Dean

MOUNT VERNON HOSPITAL

NORTHWOOD, MIDDLESEX

Technician required for the Physics Departmen Workshop Applicants must be skilled machinis and/or instrument makers Some experience c servicing X-ray therapy equipment would be a advantage Commencing salary within the rang £450 by £15(3) by £20(1) to £515 per annum plu London weighting (age 21 to 25, £20 , 26 an over £30)

Applications with the names of two referee should reach the Secretary and House Governc by February 4, 1955

UNIVERSITY OF BRISTOL

DEPARTMENT OF AGRICULTURE AND HORTICULTURE
RESEARCH STATION, LONG ASHTON, BRISTOL

Applications are invited for the following posts at the Long Ashton Research Station Assistant in Chemistry in the Cider and Fruit Products Section to be appointed under the scheme of the Ministry of Agriculture and Fisheries for research institutes Assistant in Chemistry in the Agricultural Research Council's Unit of Plant Nutrition (micronutrients), at Long Ashton These appointments will be in the Assistant Experimental Officer Grade (£342 at age 20 to £640 for men £342 at age 20 to £540 for women), with superannuation Candidates for each post should possess a recognized qualification in chemistry (minimum qualification, national certificate in chemistry) For the post in the Agricultural Research Council's unit additional qualifications in microbiology will be an advantage

Further particulars may be obtained from the Secretary, to whom applications together with copies of three recent testimonials should be addressed not later than February 12 1955

THE SECRETARY,

Research Station,
Long Ashton, Bristol

UNIVERSITY OF ABERDEEN

Natural Philosophy Department requires man already trained as Glassblower, or prepared to become Glassblower after training University will pay training expenses of suitable candidate Applicants should have done National Service, and should have manual skill Wages in range £315 to £450, according to experience and ability

Applications in writing to the Secretary, Marischal College

EAST MALLING RESEARCH STATION

Botanist required, for work connected with the effect of field factors on fruit characters especially those affecting the storage life of apples Experience in microscopy an advantage The post is in the Ministry of Agriculture's Assistant Experimental Officer grade

Further particulars and application form available from the Secretary, East Malling Research Station near Maidstone Kent, by whom applications should be received not later than February 7 1955

ONTARIO RESEARCH FOUNDATION

CANADA

Chemist preferably not over 30 years of age, is required for physical and chemical research relating to textile industrial operation Two or three years' experience in research or industry desirable

Applications or requests for further information should be addressed to Personnel Officer, Ontario Research Foundation, 43 Queen's Park, Toronto 5, Ontario

---

RESEARCH ASSISTANT SOUGHT BY THE Chemistry Department, University of Birmingham, to design and construct research electronic equipment and assist in its use Salary according to experience and qualifications Degree not essential —Applications, stating details of career, to Secretary to the Director, Chemistry Department, The University, Birmingham 15

CARTOGRAPHIC DRAUGHTSMAN (OVER 21) required by The Nature Conservancy Must be experienced draughtsman capable of plotting from aerial photographs and surveyor's notes Knowledge of hand lettering desirable but not essential Starting salary between £342 and £402 (men) according to age Annual increments of £20 to £482 and £15 to £595 Women somewhat less —Applications, giving details of sex, date of birth, education national service, technical training and experience, present appointment, and names and addresses of two referees, one to speak for ability and one for character, must reach the Establishment Officer, The Nature Conservancy 19 Belgrave Square, London, S W 1, before February 11, 1955

JUNIOR TECHNICIAN REQUIRED FOR Histology Experience laboratory work histology or biology an advantage Knowledge photography useful Salary scale £130 to £312 plus London weighting Commencing pay within scale according to qualifications and experience Superannuation scheme —Apply, with full details, to Secretary Royal Veterinary College, Royal College Street N W 1

UNIVERSITY OF MANCHESTER

Applications are invited for a full-time post as Reader or Senior Lecturer in Chemical Pathology Candidates need not be medically qualified, but should have special qualifications in chemical pathology Salary scales are (a) for medically qualified persons, Reader £1 800 by £100 to £2,250, Senior Lecturer £1,800 by £100 to £2,000, (b) for non-medically qualified persons, Reader £1,250 by £50 to £1,600, Senior Lecturer £1,150 by £50 to £1,500 (salary scales are at present under review) Initial salary and status according to qualifications and experience Membership of the F S S U and children s allowance scheme

Applications should be sent not later than February 26, 1955 to the Registrar, The University, Manchester, 13, from whom further particulars and forms of application may be obtained

---

THE UNIVERSITY OF ALBERTA ANnounces the following vacancies in Mathematics (1) Assistant or Associate Professor of Statistics, appointment to be effective September 1 1955, starting salary $5,000 or higher, normal increments $250 (2) Sessional Lecturer in Mathematics for eight months from September 1, 1955, at a gross salary of about $3 600, prospect of permanent appointment —Applications, including transcript of academic record, curriculum vitae, publications, names of two references, and recent photograph or snapshot to be sent to Walter H Johns, Dean, Faculty of Arts and Science, University of Alberta, Edmonton, Canada

---

APPOINTMENTS VACANT

BRITISH RAYON RESEARCH ASSOCIATION

Physical Chemist required, with an interest in thermodynamics and reaction kinetics, to carry out research on dye adsorption by textile materials Applicants should have a good honours degree, with some research experience (not necessarily in textiles) Salary in accordance with age and qualifications Superannuation under F S S U

Applications quoting vacancy reference P C 1 with full details and names of two referees, should be addressed to the Appointments Officer, British Rayon Research Association Heald Green Laboratories, Wythenshawe, Manchester

---

CHEMICAL ENGINEER OR INDUSTRIAL CHEMIST

with plant experience, interested in chemical engineering, is required for the Technical Group of the Company Duties will include process investigation and development and specialized equipment design Permanent appointment carrying pension and life assurance —Write, stating reference N S J5, and details of age, qualifications and experience, to

PERSONNEL OFFICER (STAFF),
MAGNESIUM ELEKTRON, LIMITED,
P O BOX NO 6, LUMM'S LANE,
CLIFTON JUNCTION, SWINTON, NEAR
MANCHESTER

GRADUATE CHEMIST, METALLURGIST or Chemical Engineer required, to deal with problems relating to the installation of electroplating plant and process control Applicants must have completed military service and be willing to travel —Apply, Electro-Chemical Engineering Co, Ltd, 161 Queens Road Weybridge, Surrey

---

BACTERIOLOGIST, WITH UNIVERSITY degree, wanted to take charge of laboratory producing veterinary sera and vaccines Must be experienced in laboratory techniques and have had at least two years' practical experience Knowledge of veterinary work an advantage, but not essential —Box 619, T G Scott and Son, Ltd, 143-147 Regent Street, London, W 1

ENGINEER AGED 22/35 REQUIRED BY Cable Company in London area for testing and maintenance of electronic equipment in new instruments for automatic testing of telecommunication cables —Apply, giving full particulars to Box 618, T G Scott and Son Ltd, 143-147 Regent Street, London, W 1

LADY CHEMIST, GRADUATE OR H N C, required for analysis of electroplating and allied solutions —Apply, Electro-Chemical Engineering Co Ltd 161 Queens Road, Weybridge, Surrey

---

THE BRITISH CERAMIC RESEARCH Association has vacancies for honours graduates in physics or chemistry, for work on a wide range of problems in the ceramic industry Previous experience in this field is not essential The appointments, which carry superannuation under F S S U, are permanent and offer good prospects Salary will depend on age, qualifications and experience, but will be within the range £450 to £800 for Scientific Officers, and £830 to £1,070 for Senior Scientific Officers —Applications, together with full details should be sent to the Director of Research, Queens Road, Penkhull, Stoke-on-Trent

---

RESEARCH METALLURGIST REQUIRED to undertake investigations on metallurgical problems associated with the machining and cold forming of metals Candidates should possess a good degree The position is permanent and there are good prospects for advancement Superannuation scheme in operation —Send full details, including age, experience, qualifications and salary required to Box 614, T G Scott and Son, Ltd 143-147 Regent Street, London W 1

WANTED A MAN TO TAKE CHARGE OF a new division on nuclear pile instrumentation The division is small at the moment but expected to expand considerably in the coming years and a very attractive career is offered to the right man Experience in servo systems and electronic circuitry is essential —Particulars, quoting reference R13, to the Personnel Officer, Ericsson Telephones Limited Beeston, near Nottingham

---

ORGANIC RESEARCH CHEMIST REquired by company manufacturing fine and technical chemicals The work will be mainly on hydrogenation of aromatic compounds, with particular reference to stereochemistry of products Honours graduates preferred, some industrial research experience desirable Initial salary up to £850 The post can be regarded as permanent and pensionable —Apply in writing, stating age and giving details of education and experience to Personnel Manager, Howards of Ilford, Ltd Ilford Essex

---

SENIOR TECHNICIAN, WITH EXPERIENCE in biochemistry and/or biology required for position of Research Assistant to the Research Manager of a company manufacturing pharmaceutical and medicinal preparations The post is a responsible one, and calls for a first-rate thorough worker, possessing keenness and initiative Contributory pension scheme —Apply to Secretary, Benger's, Limited, Holmes Chapel Cheshire

---

ELECTRON MICROSCOPE LABORATORY Assistant, male or female, educated to Inter Science or higher school certificate standard required in Record Division of Electric and Musical Industries, Ltd, to operate electron microscope for purposes of production control and research Work is delicate and calls for dexterity in preparing specimens Previous experience a recommendation, but not essential Free training to selected applicant —Write, stating age, education and previous experience, to Personnel Dept (WL) E M I, Ltd, Blyth Road Hayes, Middlesex

---

A PHYSICAL CHEMIST IS REQUIRED BY Johnson & Johnson (Great Britain), Ltd, at the Central Research Division, Slough, for investigations on the surface chemistry of textile fibres and other high polymers Applicants should hold good academic qualifications, and should preferably have had experience in the textile field Commencing salary will be not less than £750 per annum —Applications to Research Director, Research Department, Johnson & Johnson (Great Britain), Ltd, 240-242 Bath Road Slough, Bucks

---

VACANCY EXISTS FOR POSITION AS SECtion Head of Test Set Development, Design and Construction Group Age 25 to 38 years Higher national or City and Guilds telecommunications certificate essential plus detailed knowledge of radio and electronic equipment Experience of R F measurements and test equipment an advantage House could be made available —Apply in writing to the Personnel Manager, Standard Telephones and Cables, Limited, Crystal Division Industrial Estate East, Harlow, Essex

---

BRITISH NYLON SPINNERS, LTD, HAVE a vacancy in their Library and Information Section for a woman graduate in chemistry She will be mainly concerned with assisting members of the Research and Development Departments in their work by carrying out searches in scientific literature, and with the selection of information of interest from new material as it is published Previous library experience is not essential The appointment is permanent and pensionable —Apply in writing to Personnel Manager, Pontypool Mon

MOTOR INDUSTRY RESEARCH ASSOCIATION

DEPUTY DIRECTOR

Applications are invited for the newly-created post of Deputy Director of the Motor Industry Research Association Candidates must have high academic qualifications, wide experience in engineering research and, preferably, some administrative ability and a knowledge of the motor industry A salary up to £2,000 per annum will be paid to a suitably qualified candidate and superannuation provided under the F S S U scheme

Apply in writing, giving full details of qualifications and experience, to Director, Motor Industry Research Association, Lindley, near Nuneaton, Warwickshire

---

STEAM GENERATING PLANT

Considerable opportunities are arising in an established and rapidly growing concern engaged in the design and manufacture of large steam generating plant, including new developments Applications are invited from Engineers under 35 years of age with qualifications and experience in one or more of the following branches

(a) Steam boiler plant design generally
(b) Heat transfer design
(c) Combustion engineering design on all fuels
(d) Structural design

The qualifications under (b) (c) and (d) need not necessarily be in the steam engineering field

Applications, which will be regarded as strictly confidential, should be written in the first instance and addressed to Dr R S Silver, John Brown Land Boilers, Limited Whitecrook Works, Clydebank

---

PHYSICIST REQUIRED BY A RESEARCH group of a well known Company in West London area Applicants should have good academic qualifications and research experience involving infra-red techniques The post offers considerable opportunity for original work and carries excellent salary and prospects —Please write in confidence, with full details, to Box 624, T G Scott and Son, Ltd , 143-147 Regent Street, London, W 1

JOSEPH LUCAS, LIMITED, HAVE AN INTERESTING vacancy in their research and development laboratories which would be suitable for a young graduate with honours degree in mathematics or physics The work is largely of a fundamental nature and is concerned with acoustics and mechanical vibrations Previous industrial experience is not necessary —Please reply, giving qualifications, age, and any other relevant details, to Personnel Manager, Joseph Lucas (Electrical) Ltd , Great King Street, Birmingham quoting reference PM/D/59

JOHNSON & JOHNSON (GREAT BRITAIN) Ltd , require a qualified Microbiological Chemist in the Central Research Division, Slough This is solely a research appointment and will not involve routine testing Research experience involving bacteriology and/or mycology is essential Commencing salary according to qualifications and experience —Apply to Research Director, Johnson & Johnson (Great Britain), Ltd , Research Department, 240-242 Bath Road, Slough, Bucks

---

LEADING OIL COMPANY HAVE VACANCY for Chemist in their Head Office Applicants should be in possession of degree or equivalent, and if possible wide experience in the petroleum industry Work to cover lubricants, solvents, bitumens, fuels, etc Age 30 to 35 years Salary according to age and qualifications —Applicants should apply, giving full particulars of qualifications and experience, quoting H 3115 to Box 7204 c/o 191 Gresham House E C 2

PHYSICAL METALLURGIST IS REQUIRED by Imperial Smelting Corporation Ltd , for laboratory investigational work on alloys This is a Senior Staff appointment in the Research Laboratory of the Organization and applicants should possess a degree in metallurgy or equivalent qualification and not less than one years' industrial experience in physical metallurgy work Commencing salary will be dependent on individual qualifications and experience and applications should be submitted to Personnel Manager, Imperial Smelting Corporation Ltd , St Andrew s Road Avonmouth quoting reference MRL/N

RESEARCH AND DEVELOPMENT Ferodo, Limited, have vacancies for both Technical Assistants and graduate Technical Officers The Assistants should preferably have advanced level G C E in physics or chemistry, while some industrial experience, particularly of moulding or related technologies, would be advantageous The work is concerned with the development of various types of friction products and offers good opportunities for men with initiative and enthusiasm for the development of products in a new field Contributory pension scheme compulsory —Applications giving full details of age, education, industrial experience etc , and quoting T/RAD, to Personnel Manager, Ferodo, Limited, Chapel-en-le-Frith, via Stockport

---

MEDICAL REPRESENTATIVES BRITISH subsidiary of leading American ethical pharmaceutical house have vacancies in several areas for Medical Representatives Good starting salary and expenses Car provided —Applications with full particulars of age, qualifications, experience and salary required, in writing only, to the Manager, Pfizer, Ltd , 137-139 Sandgate Road, Folkestone, Kent

---

THE B T H COMPANY HAVE A vacancy in their Research Laboratory for a Chemist or Physicist to engage in the preparation and processing of silicon for use as a crystal rectifier at ultra-high frequency —Applicants should possess a degree in physics or in chemistry and should write, giving their age and other particulars to the Director of Research, British Thomson-Houston Co , Ltd , Rugby, quoting Reference ATJ

PROFESSIONALLY QUALIFIED ENGINEERS and Physicists are required to explore and develop new circuits based on transistors —Applicants should write to the Director of Research British Thomson-Houston Co , Ltd Rugby, quoting reference BR and stating their age qualifications and experience

---

THE B T H COMPANY HAVE vacancies in their research laboratory for Assistants in the production, treatment and processing of silicon in very pure form Applicants should have some chemical knowledge and preferably hold a national certificate in chemistry or physics —They should write, giving their age and other particulars to the Director of Research British Thomson-Houston Co , Ltd , Rugby, quoting reference ON

TECHNICAL SALES REPRESENTATIVE, age 25 to 32 of good approach, required by well known Company, to specialize in non-selective weed control products Knowledge of soils, weeds and mechanical appliances desirable Five-day working week —Apply in writing, stating qualifications and salary required, to Box 8253, c/o Charles Barker & Sons Ltd , 31 Budge Row, London, E C 4

ANALYTICAL CHEMIST THE BRITISH Drug Houses Ltd , Graham Street, London, N 1, require an Analytical Chemist for work on the analysis of organic pharmaceutical compounds Candidates should be of B Sc standard Previous experience desirable but not essential Salary according to qualifications and experience Five-day week, canteen, sports club, pension and profit sharing schemes —Write, stating age, experience, if any to the Staff Manager

---

APPLICATIONS ARE INVITED FROM RECENTLY qualified male Chemists for interesting progressive post in cereal laboratory Work will involve non-routine analysis and research Applicants should be in 20 to 25 age group Five-day week and pension scheme in operation —Write, giving full particulars of academic qualifications and experience to Personnel Manager (L), Quaker Oats, Limited Bridge Road, Southall, Middlesex

---

ENGINEER AGED 25 /35 WITH ELECTRICAL or physicist degree required by Cable Company in London area for development work on testing equipment for telecommunication cables Permanent and pensionable position at salary commensurate with experience and qualifications —Apply, giving full particulars to Box 617 T G Scott and Son, Ltd , 143-147 Regent Street, London W 1

AN INFORMATION SCIENTIST IS REQUIRED for the Central Research Department of the Morgan Crucible Co , Ltd A good degree, preferably in general science, is essential, and a knowledge of French and German would be useful The successful applicant must be able to prepare lucid reports on a wide variety of scientific subjects, and (a) collect and disseminate scientific information , (b) take an active and direct part in all research projects in advising research workers and keeping them up to date with information relevant to their particular project , (c) administer the Technical Library and Information Department —Details of experience, age and qualifications should be sent to the Staff Manager, Battersea Church Road S W 11

IMPERIAL SMELTING CORPORATION Limited has vacancy for Inorganic or Physical Chemist to work on problems of pigments manufacture in research laboratory Applicants should possess minimum second-class honours degree in chemistry and should preferably have two to three years' research experience Commencing salary will be fixed according to individual qualifications and experience —Applications in first instance, quoting reference CMP/N, to Personnel Manager, Imperial Smelting Corporation Ltd , St Andrews Road, Avonmouth, Bristol

---

IMPERIAL SMELTING CORPORATION has a vacancy for a Group Leader in Surface Chemistry Section of Research Laboratory to supervise a small group carrying out research i vestigations on the surface chemistry of pigment Applicants should possess an honours degree i chemistry and knowledge or experience in surfac chemistry, colloid chemistry or related fields — Applications, quoting reference GLS/N, tc Personnel Manager, Imperial Smelting Corporation Ltd , St Andrew's Road, Avonmouth, Bristol

---

ENGINEER WANTED BY IMPERIAL Chemical Industries Ltd , Alkali Division, Winnington, Northwich, Cheshire, to do research on industrial chemical operations such as heat transfer and matter transfer Candidates aged 25-35 should possess an honours degree in engineering (preferably mechanical) and have received such practical training as is required for Associate Membership of the major Engineering Institutions Starting salary according to age and experience — Applications, giving details of age and experience should be addressed to Staff Manager

---

THE WELLCOME FOUNDATION LIMITED invites applications from graduates, either men or women, for posts as Biochemists at the Wellcome Research Laboratories (Biochemical Division), Beckenham, Kent Applicants should possess an honours degree in biochemistry and should preferably have some knowledge of physiology Salary will be in accordance with age, experience and qualifications —Applications should be made in writing to the Head of the Biological Division, The Wellcome Research Laboratories, Beckenham Kent

---

ENGLISH ELECTRIC CO , LTD , WISH TO extend their present laboratory facilities for study of the effect of environmental conditions on guided weapons and their components Applications are therefore invited from Senior an Junior Engineers to direct and carry out it work A wide variety of electrical, mechanical and physical testing is under consideration, and, although previous experience of guided weapons is desirable, it is by no means essential The possession of an engineering or physics degree, H N C , or similar qualification coupled with some experience in designing and handling ingenious electrical and mechanical test contrivances, would form a satisfactory qualification Housing assistance can be given if required —Please write stating age, experience and qualifications, to Dept C P S , 336-7 Strand, W C 2 quoting Ref 1000E

IMPERIAL CHEMICAL INDUSTRIES, DYESTUFFS Division, have a vacancy in their laboratories in the Manchester district for a young woman honours graduate who has specialized in biological science, preferably with some experience in microbiology The appointment is concerned with biological control and the manufacture of antibiotics —Applications, giving full particulars of age, qualifications and experience should be addressed to the Staff Department Hexagon House, Blackley, Manchester 9

APPLICATIONS ARE INVITED FOR POSTS in a development laboratory located in Northamptonshire Minimum qualification required is a degree in physics or the equivalent Experience in microwave work would be advantageous —Box 628, T G Scott and Son, Ltd , 143-147 Regent Street London W 1

A PROFESSIONALLY QUALIFIED Engineer or Physicist is required for the development of electrical spark erosion methods as applied to the cutting of hard metals —Applicants should write to the Director of Research British Thomson-Houston Co , Ltd , Rugby, quoting reference BL and stating their age qualifications and experience

WELL-KNOWN COMPANY LOCATED west of London requires a Librarian for its expanding Research Department Duties will consist essentially of the collation, indexing and dissemination of technical information Candidates should preferably hold a degree in chemistry and have had experience in literature research Detailed knowledge of cataloguing and indexing methods is essential This is a new and responsible post, and attractive salary, commensurate with qualifications and experience, will be paid —Write Box N 941, LPE 55 St Martin's Lane, W C 2

IMPERIAL CHEMICAL INDUSTRIES LTD , has a vacancy for a male Assistant Botanist for research on plant growth regulators Candidates must be under 30 and hold an honours degree in botany Some plant physiological research experience is essential —Write with details of education, qualifications and experience to the Secretary, Jealott's Hill Research Station Imperial Chemical Industries, Ltd Bracknell, Berks, before January 31, 1955

INDUSTRIAL ORGANIZATION CONcerned with application of photographic processes and apparatus requires a first-class Senior Assistant to undertake comprehensive duties in its Patent Department Interests are world-wide An extensive knowledge of patent procedures is necessary —Write Box 626 T G Scott and Son, Ltd , 143-147 Regent Street London W 1

ASSISTANT STATISTICIAN WITH DEGREE in mathematics and/or statistics (or equivalent) required, for work in connection with development—and production—investigations He/she will be directly responsible to the Company's Industrial Statistician Previous experience not essential The post offers excellent prospects and carries senior staff status Contributory pension scheme —Applications, giving details of age education, qualifications, etc , and quoting reference T/AS to Personnel Manager, Ferodo, Limited Chapel-en-le-Frith, Via Stockport

YOUNG MEN OF GRADUATE STANDARD in science required as Shift Technicians Interesting and responsible positions with scope for advancement Some knowledge of photography an advantage Non-contributory pension and insurance plan —Apply by letter to Personnel Department Kodak, Limited (Factories), Wealdstone, Middlesex

APPLICATIONS ARE INVITED FOR THE appointment of Chief Development Engineer by established Electrical and Scientific Instrument Manufacturers Candidates must possess good academic qualifications and have extensive experience in the design and development of light electro-mechanical and electronic precision instruments The post is an important one carrying with it the responsibility of control and administration of existing staff of physicists engineers, drawing office and prototype personnel —Applications which will be treated in strict confidence, should state details of qualifications, experience, etc , and be addressed to the Managing Director R B Pullin and Co Ltd , Phoenix Works, Great West Road, Brentford, Middlesex

BIOCHEMIST THERE IS A VACANCY for a Biochemist in the Wellcome Laboratories of Tropical Medicine The work of this appointment consists mainly in the investigation of problems relating to the action of chemotherapeutic drugs, and experience in this or some similar field is essential The salary offered will be governed by the age and qualifications of the candidate —Applications should be addressed to the Secretary, Wellcome Laboratories of Tropical Medicine (The Wellcome Foundation, Ltd), 183 Euston Road London, N W 1

GRADUATES WITH HONOURS DEgree are required by the BTH Co , Rugby for research into the physics of light emission from electric discharges and from incandescent surfaces The work will involve radiation measurement and the experimental development of new light sources —Applicants should write to the Director of Research, British Thomson-Houston Co Ltd , Rugby, giving their age, qualifications and college, quoting reference RH

GLAXO LABORATORIES LTD , YOUNG Writer of sound education with some scientific knowledge required in creative team dealing with interesting scientific material Work includes writing technical literature and articles for medical, veterinary and pharmaceutical professions Literary ability, enthusiasm and lively interest in medical developments essential , background in physiology or allied fields could be valuable Superannuation and incentive schemes —Apply with specimens of original writing, if available to Senior Personnel Officer, Glaxo Laboratories Ltd , Greenford, Middlesex

CHEMIST OR PHYSICIST GRADUATE preferred, with some industrial experience, to assist in development of sub-miniature electronic components Knowledge of new materials and processes and their applications in this field is desirable —Write, giving details of experience and salary required, to Manager, Component Division, Fortiphone, Ltd , 247 Regent Street London, W 1

Advertisers please note You must add "Apply Employment Exchange" unless the employment advertised or the workers required are excepted under the Notification of Vacancies Order

BRITISH NYLON SPINNERS, LIMITED The Company's expanding activities will give rise to further appointments, during the next few months, covering a wide field of scientific endeavour Graduate Scientists and Textile Technologists whether available now or later, are invited to register their interest at this stage and where necessary exploratory interviews will be arranged involving no obligation The openings will cover a range of work including pure research, applied research plant experimentation and the development of new manufacturing techniques up to full scale operation For men with suitable ability and inclinations there will be opportunities for specializing in the new advanced forms of technology arising with the advent of synthetic fibres and their textile applications Several of the appointments will be at a senior level, and the Company will welcome tentative inquiries from chemists, physicists and textile graduates —These will be treated in strict confidence, and should be addressed to the Personnel Manager, British Nylon Spinners Limited, Pontypool Mon

A WELL-ESTABLISHED COMPANY WITH a dominant position in its own field requires a man as Assistant to the Manager The first assignment would be to take charge of a small investigating team to review all processes and procedures of the whole manufacturing process with a view to recommending constructive changes A man of proved ability is required who understands people as well as processes preferably he should be not more than 35 years of age with a liberal education and some experience in engineering or physics, though other forms of experience or training are not excluded The first assignment should automatically lead to a position of responsibility and authority and the job will command a good salary —Write Box 627, T G Scott and Son, Ltd 143-147 Regent Street, London, W 1

CHEMIST OR BIOCHEMIST FOR ANAlytical and research work, bacteriological experience an advantage Age 21 to 30 —Box 625 T G Scott and Son, Ltd , 143-147 Regent Street, London W 1

GRANTS & SCHOLARSHIPS

LONDON COUNTY COUNCIL

ROBERT BLAIR FELLOWSHIP IN APPLIED SCIENCE AND TECHNOLOGY

Applications are invited for the award of the Robert Blair Fellowship tenable for one year of advanced study or research abroad in applied science and technology The value of the award is subject to variation, and if the country selected should be Canada or the U S A may be about £1,000, subject to P A Y E deductions Candidates must be British subjects and at least 21 years of age

Further particulars and application forms obtainable from the Education Officer (EO/H1/2), The County Hall, London S E 1 (s a c (foolscap) necessary), and returnable by March 1, 1955 (1659)

NUFFIELD FOUNDATION

SOCIOLOGICAL SCHOLARSHIPS AND BURSARIES

The Nuffield Foundation, in pursuance of its programme for the advancement of sociological studies, is prepared to offer for the academic year 1955-6 a small number of scholarships and bursaries to enable graduates in academic subjects other than the social sciences, psychology or economics, to study the social sciences The Foundation's particular object is to enable men or women, who are already well qualified in other disciplines, particularly the natural sciences or the humanities, to receive a training in for example, political science, social psychology, anthropology, social statistics and sociology generally (but not economics) so that in due course they may undertake research or teaching in the United Kingdom in those subjects The scholarships, which are the senior awards, are intended for persons who have already undertaken some postgraduate work in their own subject The bursaries are intended to enable those who have recently graduated to take a course of training in sociological subjects In the case of both scholars and bursars the Foundation will pay the cost of university and/or college fees in addition to a maintenance award Graduates of universities in the United Kingdom, of either sex and preferably between the ages of 22 and 35, are eligible to apply

Applications for awards in 1955 must be received before May 1, 1955, by the Director, The Nuffield Foundation, Nuffield Lodge, Regent s Park, London, N W 1, from whom full particulars and application forms can be obtained

L FARRER-BROWN
Director of the Nuffield Foundation

THE ROYAL SOCIETY

JOHN MURRAY TRAVELLING STUDENTSHIP IN OCEANOGRAPHY AND LIMNOLOGY

The Council of the Royal Society is prepared to receive applications for the John Murray Travelling Studentship in Oceanography and Limnology The Studentship is open to male British graduates under the age of 35 and is to be used for the encouragement of travel and work in oceanography or limnology The value of the Studentship will be between £500 and £600, and it may be awarded for a period of one year or less It is hoped that students will try to gain practical experience of deep-sea oceanography, as initiated by the Challenger Expedition though this is not a condition of the award, which is available also for limnology for this purpose they can be assisted in arrangements to sail in oceanographic research ships as opportunities arise Students may be enabled also to visit and work at oceanographical institutions and research stations abroad

Applications which should be received not later than February 10 1955 may be made on forms to be obtained from the Assistant Secretary Royal Society Burlington House, Piccadilly, London, W 1

NUFFIELD FOUNDATION

BIOLOGICAL SCHOLARSHIPS AND BURSARIES

The Nuffield Foundation, as part of its pr gramme for the advancement of biological studie is prepared to offer for the academic year 1955- a limited number of scholarships and bursar to enable persons who have graduated in physi chemistry, mathematics or engineering, but wh have had no training in a biological subject, receive such training in biology as will enab them in due course to undertake research a teaching in the United Kingdom in the biologic sciences The scholarships, which are seni awards, are intended for persons who have a ready undertaken some postgraduate research i their own subject The bursaries are intended t enable those who have recently graduated to complete a course of training in biological subject including if considered necessary, a full hono degree course in biology In the case of bot scholars and bursars the Foundation will pay th cost of university and/or college fees in additio to a maintenance award Graduates of universities in the United Kingdom, of either sex an preferably between the ages of 22 and 35, ar eligible to apply

Applications for awards in 1955 must be re ceived before April 1, 1955, by the Director, Th Nuffield Foundation Nuffield Lodge, Regent Park, London, N W 1, from whom further par ticulars and application forms can be obtained

L FARRER-BROWN
Director of the Nuffield Foundatio

SCHOLARSHIPS ABROAD, 1955-5

Applications are invited from British student for Scholarships offered by Austria, Belgium Brazil, Denmark, Finland, France, Germany, Ice land, Italy, The Netherlands, Norway, Persia Portugal, Spain, Sweden, Switzerland and Yugo slavia The awards are mainly for universit graduates and undergraduates, and are tenabl for periods varying from a few weeks to twelv months during the academic years 1955-56 Th closing dates for receipt of applications vary fo each country, the earliest being March 7, 1955

Full particulars and application forms, fo which a stamped, addressed foolscap envelope should be sent, are obtainable from the British Council, 65 Davies Street, London, W 1, or fr any British Council Office in the United Kingdom

LONG WORKING DISTANCE ATTACHMENT

provides a working distance of 12 8 mm between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm objective.

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

★*Critical* VACUUM LEAK TESTING applied *ECONOMICALLY*

Working with critical vacuum processes or hermetically sealed instruments, such as mercury arc rectifiers, electron tubes, etc., slow leaks can prove extremely costly Utilising a simple 'tracer-gas' technique, EDWARDS PALLADIUM - BARRIER LEAK TESTER is a highly accurate and reliable instrument with a sensitivity approaching that of the mass-spectrometer—but without its complications or expense

Best results are obtained, as with all detection systems, when used with a pumping system specially designed for leak testing **Standard leak test pumping systems are manufactured by W Edwards Send for full details**

Built by Craftsmen . . . . *Pye Precision Vernier Potentiometer*

ACCURACY WITHIN YOUR GRASP

Designed for measurements of a very high order of accuracy, this VERNIER potentiometer is being used extensively for the accurate measurement of resistance, as a standard for calibrating potentiometers, meters and other electrical measuring instruments, for measuring thermo-couple voltages and for many applications of a similar nature. Through every stage of its manufacture the most careful precautions are taken to eliminate possible sources of error

Please write for details of our range of precision potentiometers which also includes a SLIDE-WIRE type reading to 1 microvolt with an accuracy of 02% as well as a PORTABLE type which is completely self-contained, compact, robust and always ready for immediate use.

Our new catalogue giving details of our comprehensive range of Galvanometers, Shunts, Standard Cells and other precision measuring instruments is available on request. May we please send you a copy?

Wherever you need distilled water — in laboratory, factory or shop — you can use 'Deminrolit Water' with equal results. The Portable 'Deminrolit' plant operates by ion exchange and delivers water substantially free from dissolved solids. Running costs are measured in pence instead of in pounds, and you can thus use distilled quality water for many purposes where the cost of distillation would prove prohibitive. Please write for Technical Publication No. 62 which gives full details.

HIRE SERVICE

Why not try demineralised water in your industry? You can do so easily and cheaply by hiring from us, at a nominal rental for a trial period, the latest Mark II Model Portable 'Deminrolit' Plant. Details of this service will gladly be supplied on request.

a New STABILISED POWER SUPPLY UNIT FOR PHOTO-MULTIPLIERS

Ediswan now have available a new stabilised power supply unit which has been specially designed to feed Photo-Multipliers. It is particularly suitable as a supply unit for Ediswan Mazda Photo-Multipliers type 27 M1, 27 M2 and 27 M3

BRIEF SPECIFICATION				
INPUT	OUTPUT	STABILITY	OUTPUT RESISTANCE	RIPPLE
200–250 v, 40–100 c p s	High stability low ripple D C supply variable between 300 and 1,100 volts Max current 2 mA Pos or neg may be earthed	A 10% change in mains input voltage results in a change of less than 0·1% between 1,100 volts and 600 volts output	Approximately 1,500 ohms	Less than 0·01% R M S
MOUNTING The Unit is suitable for standard rack mounting or for bench use Bench Stands are available				

PRICE — £48

Further information is available on request

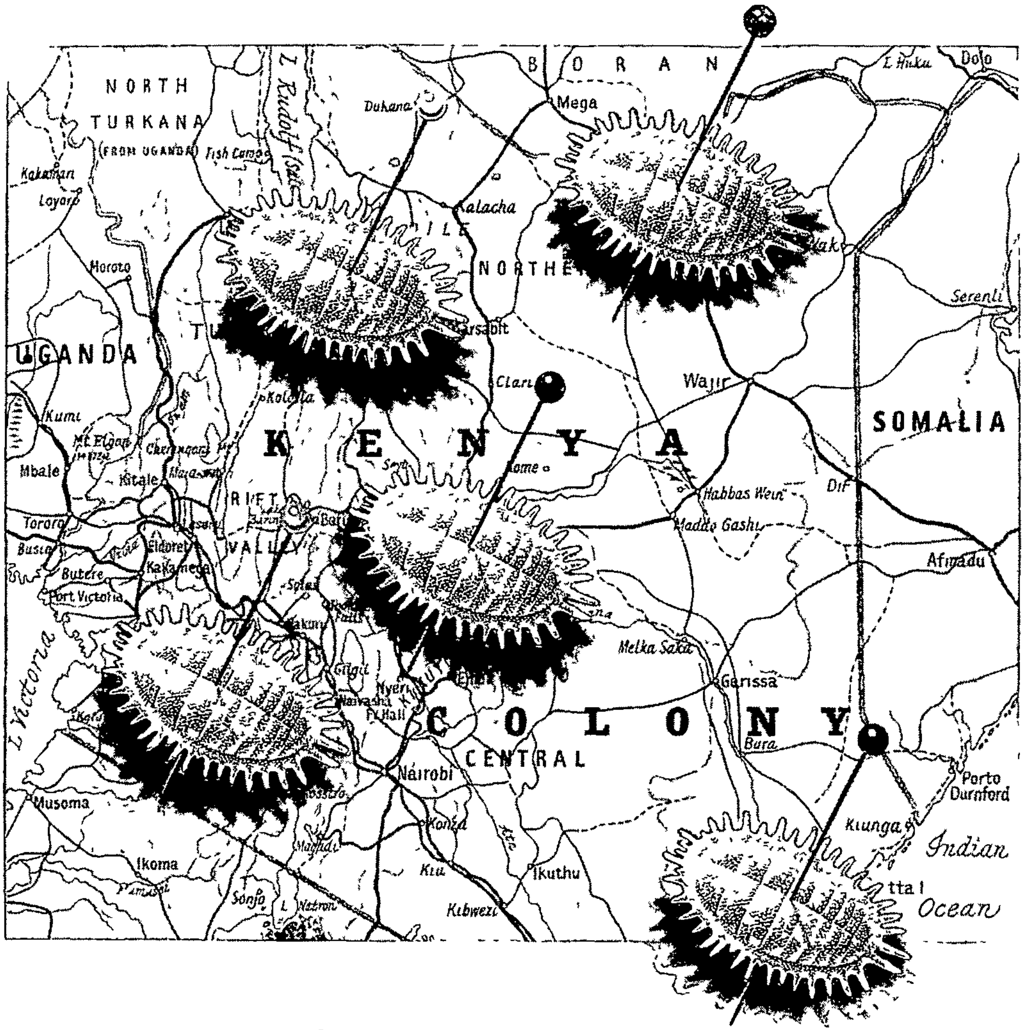
SP115



The case of *Pseudococcus kenyae* . . .

P. kenyae is a mealy bug which feeds on the sap of Kenya's coffee trees and spreads disease through the plantations. Given the chance, predatory insects soon clean up infestations — but between the mealy bug and the predators stands a species of ant. In return for a secretion of 'honeydew' the ants protect the mealy bugs from their natural enemies.

Direct control of the pest has always been difficult, because mealy bugs wear waxen coats which throw off insecticides. However, Kenya coffee growers have solved the problem by using the Shell insecticide dieldrin — against the ants.

Dieldrin is a powerful and persistent ant destroyer. One low-cost application to the stems of the trees acts as a lethal barrier to the ants for at least two months, by which time the predators have moved in and killed the mealy bugs.

Dieldrin is one of the newer Shell insecticides, effective against a very wide range of crop-destroying pests. Its exceptional persistence, surer kill and lower dosages are now aiding agricultural production throughout the world. It is also extensively used as a residual spray against disease carrying insects.

Aldrin — another recent Shell development — is fast becoming recognised as the best of all insecticides for the control of pests in the soil.

Is there an urgent pest problem in your area?

dieldrin

dieldrin and aldrin are SHELL insecticides for world-wide use

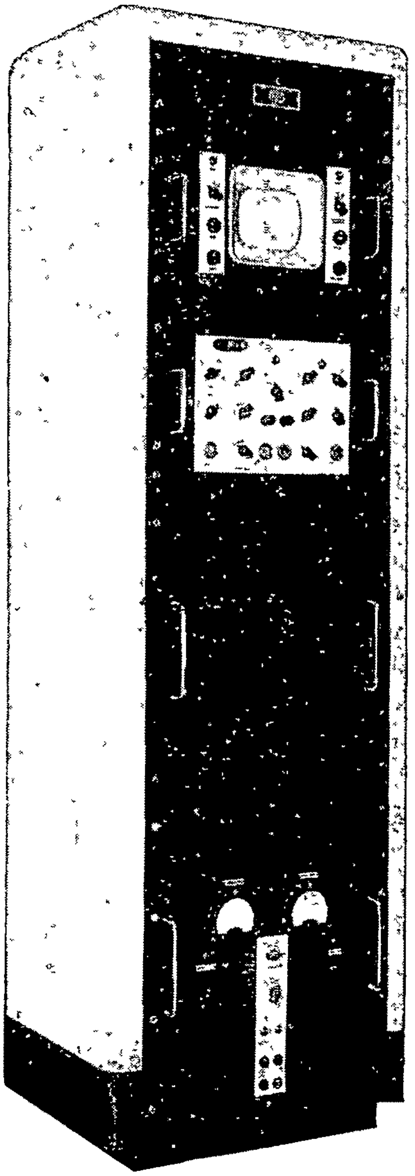
PROGRESS IN CONTROL

**SUNVIC
PULSE HEIGHT
ANALYSER**



An instrument for the analysis of a complex pulse amplitude spectrum into groups of known height according to their voltage amplitude.

It displays up to a maximum of 120 channels and can store 1,200 binary digits The design is based on that of Hutchinson & Scarrott (*Phil Mag.*, 42, 792, 1951) and the instrument is made under licence from the N R.D C.

EQUIPMENT BY SUNVIC

SUNVIC CONTROLS LTD *(Special Products Division)*, *No 1 Factory, Eastern Industrial Estate, Harlow, Essex* Telephone Harlow 24231/5

CASEIN

LOW VITAMIN CONTENT

In the field of research on animal nutrition a Casein of low vitamin content is required as a vitamin-free animal protein base. *Casein — low vitamin content* — as supplied by Whiffens, has a protein content of not less than 90% The process by which it is made is designed to remove both fat and water soluble vitamins, making the product suitable for the usual biological depletion procedures. It conforms to the following general specification:—

Appearance	**Cream coloured powder**
Loss at 100°C	**Not more than 5%**
Protein (by Nitrogen)	**Not less than 90%**
Ash	**Not greater than 2.0%**
Aneurine Hydrochloride	**Not greater than 1 pt. per million**
Riboflavin	**Not greater than 0.25 pt. per million**
Nicotinic Acid	**Not greater than 1 pt. per million**
Pantothenic Acid	**Not greater than 0.75 pt. per million**

Analyses of individual batches are available on application
Available in units of 3 Kgs packed in hermetically sealed tins

Each consignment of CASEIN-LOW VITAMIN CONTENT
is identified by a batch number.

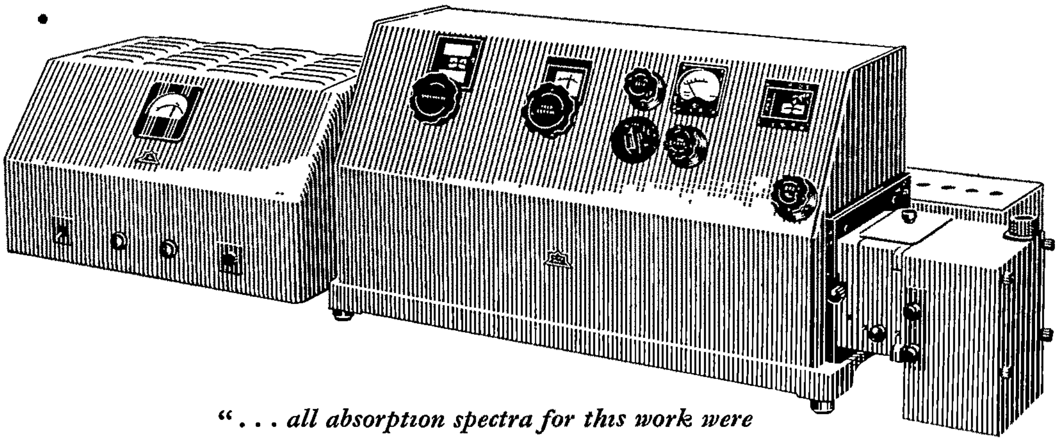
RELIABLE IN ALL WORKING CONDITIONS

"... the most convenient method was found to be ultraviolet absorption measurement ..."



"... all absorption spectra for this work were measured with a Unicam Quartz Spectrophotometer model SP 500 .. "

The frequency with which the Unicam SP.500 is mentioned in the literature is convincing proof of the sustained quality of its performance and of the wide variety of applications for which it is particularly suitable. For the maintenance of standards of both raw materials and the final product, for academic and medical research, wherever there is a problem of analysis or control, the easiest, most efficient, most economical answer may well be the Unicam SP.500 Spectrophotometer.

An illustrated leaflet describing the instrument in detail will gladly be sent on request.

UNIVERSITY EDUCATION IN CENTRAL AFRICA

TEN years ago, the University of London accepted a special responsibility concerning the development of higher education in the Colonial territories of the British Commonwealth The aim of the University's action was the fostering of ultimately independent and autonomous Colonial universities, and for this purpose there was formed in 1944 a Committee of the Senate for Higher Education in the Colonies This Committee—not to be confused with the Inter-University Council for Higher Education in the Colonies—had the task, among others, of considering the applications of Colonial university colleges for acceptance into what came to be known as 'special relationship' with the University of London. The latest applicant for entry into special relationship has been the new multi-racial Rhodesia University College, the origins of which have previously been discussed (*Nature*, 172, 1 , 1953 , 173, 1007 , 1954)

In its special relationship with such institutions, the University of London has an interest in almost every aspect of their development, especially in the academic standing of the staff, in the appointment of which it plays an active part. Another important matter is the level which a candidate must reach in order to gain entry to the college The degrees granted are those of the University of London, and the final decision on syllabuses and examinations rests with that University for so long as the special relationship exists In some Colonial territories the secondary school system is not sufficiently developed to enable candidates from school to attain the normal standard of entry to the University of London. Since the ultimate standard attained is fixed—that of a bachelor's degree of the University of London—the ordinary course of study in the relevant university college is, in such instances, longer than that laid down by the general regulations of the University of London

The inaugural board of the Rhodesia University College has recently decided to ask the University of London to make no special concession with regard to the entrance requirements for its College. In the Federation of Central Africa, the Cambridge Oversea School and Higher Certificate examinations are taken in the secondary schools. For admission to the University of London a candidate normally needs to possess a General Certificate of Education with passes in prescribed subjects, of which at least two must be at the Advanced level, but passes in principal subjects of the Cambridge Oversea Higher School Certificate are accepted as equivalent to passes in the General Certificate at Advanced level. The University also accepts credit passes in subjects of the Cambridge Oversea School Certificate as equivalent to ordinary passes in the General Certificate examination. The high level of entrance standard demanded by the Rhodesia University College will keep the number of non-European entrants to a small proportion of the total when the College opens in 1956 But one may hope that with an adequate intake of European students, competition for entry will lead to a rapid expansion in the number of African secondary schools in the Central African Territories which include sixth forms, and a rise in the size of the sixth forms in those schools which already teach at sixth-form level The muster of teachers suitably equipped to partake in such an expansion may well become a limiting factor, and the availability of school-teachers will itself depend in part upon the flow of graduates from the Rhodesia University College The conditions to be expected at first are therefore unlikely to lead to the immediate appearance of a large number of non-European graduates in Central Africa Nevertheless, the importance can scarcely be overrated of the new multi-racial College as a contribution to the higher education of the African at a most significant period in the history of the continent. Those who complete the full course will have reached a high and internationally recognized standard of university education, and the number of Africans who graduate each year will certainly rise early in the College's existence.

According to present plans, the Rhodesia University College will open in 1956 with Faculties of Arts and Science, and a Faculty of Agriculture also may be among the first to be instituted. The Faculty of Arts is expected to include, from the beginning, departments of English, modern languages, Latin, history, economics, African studies, and education. The Faculty of Science will cover mathematics, physics, chemistry, zoology, botany and geography Later will follow Faculties of Law and Medicine, and still later Engineering, Architecture, Music and Fine Arts In due course, special relationship with the University of London will cease, and Rhodesia University College will thereupon become a university granting its own degrees.

The financing of a new university is difficult enough in any country , but in a Federation the European inhabitants of which do not exceed a quarter of a million, it is indeed a problem. Of the £2,000,000 which will, according to estimates, be required for capital expenditure during the early years of the University College's existence, £1,250,000 has been promised from the Colonial Development and Welfare Fund and about £300,000 subscribed in the Federated Territories The recurrent costs are expected to reach not less than £250,000 per annum by 1961, and however generous the endowments may then prove to have been, a significant proportion of the current income will clearly have to be provided by the Federal Government. The growing dependence of universities upon government support is an inescapable condition of the development of higher education at the present time

In a country where racial tension can arise, the position of a multi-racial university is especially important Some of the difficulties to be faced in such a university are indicated elsewhere in this issue (p 186) in an article by the Vice-Chancellor of the University of Malaya, an institution which had the advantage of building on two established colleges. The declared aim of the Central African Federation is a partnership between the races, European and non-European, and to the attainment of this ideal a university, with the goodwill of the people and the support of the government, can make a tremendous contribution. The working out of partnership in all its details must depend vitally upon the co-operation of educated people of all kinds The Moffat Resolutions adopted by the Legislative Council of Northern Rhodesia on July 29, 1954 (*The Times*, August 14, 1954), began the task of defining partnership in a more precise way than has hitherto been attempted "(1) The objective of policy in Northern Rhodesia must be to remove from each race the fear that the other might dominate for its own racial benefit and to move forward from the present system of racial representation in the territorial legislature towards a franchise with no separate representation for the races (2) Until that objective can be fully achieved a period of transition will remain during which special arrangements in the Legislative and Executive Councils must continue to be made so as to ensure that no race can use either the preponderance of its numbers or its more advanced stage of development to dominate the other for its own racial benefit (3) During this period of transition, special legislation must be in force to protect, to the extent that may be necessary, the interests of either race Meanwhile this Council notes and agrees with the statement of the Secretary of State that it is the duty of Her Majesty's Government to ensure that on contentious issues the balance is fairly held (4) Every lawful inhabitant of Northern Rhodesia has the right to progress according to his character, qualifications, training, ability and industry, without distinction of race, colour, or creed". The significance of education, and particularly the education of the African, in the working out of such a plan must be clear to all.

The inaugural board of the Rhodesia University College has expressed its deep appreciation of the great educational services rendered by the universities of South Africa to the territories of the Central African Federation over a long period of years It has also recorded its pleasure at the many messages of goodwill received from South African universities when the foundation stone of the Rhodesia University College was laid by the Queen Mother in July 1953 The inaugural board believes that these tokens of goodwill are a sign of the interest and support of the universities of South Africa which the new College will retain in the future. Universities in Great Britain also will wish to support in their several ways a university institution of such outstanding significance to the future of the British Commonwealth.

MEDICAL BIBLIOGRAPHY AND ITS PROBLEMS

The Development of Medical Bibliography
By Dr Estelle Brodman Pp ix+226+3 plates. (Publication No. 1.) (Baltimore Medical Library Association, 1954.) 5 dollars.

THE problems of medical bibliography are cognate with those of scientific bibliography in general, and this small book will therefore be of interest to a wider circle than that for which it is primarily intended. The task of the medical bibliographer may be adequately described in the author's phrase · "to cover the entire medical literature, in whatever form, wherever published, and in whatever language, and to cover it accurately, promptly, and in easily usable form". The history of this subject has been dealt with in scattered communications for different periods and subjects, but this work is the first attempt to give a comprehensive history If the generic subject 'medicine', embracing as it does several undoubted 'sciences', is accepted as a science, then there is probably no subject in the whole range of scientific literature which has been so well served by the bibliographer. The success of his efforts in the past and in the present should therefore be of great interest to all who view with misgiving, and even alarm, the enormous increase in the literary output relating to all the sciences

Miss Estelle Brodman has wisely limited her field to the subject of medicine in general, and has excluded works dealing only with its subdivisions and specialties The general medical bibliography deals with these subdivisions, though less thoroughly than the specialized bibliographies of these subjects. Further, the specialized bibliography is a comparatively late arrival in the field. The early bibliographies were all comprehensive works which invited consultation on any subject relating to the art of medicine

The earliest medical bibliographies were poor things when examined with our present critical knowledge, and such as the historian still consults to-day he tends to find time-consuming and tiring to the eye. Of those published in the sixteenth century, the first was the "De medicinae claris scriptoribus" (1506), by Symphorien Champier, and the first subject-bibliography was that of Israel Spach Champier's work was printed in black-letter after the style of a late fifteenth-century manuscript The medical bibliography of Conrad Gesner was never published In the seventeenth century the custom of listing authors under their surnames instead of under their forenames became very general, the imprint was given regularly for each edition, and the number of cross-references relating to both authors and subjects was greatly increased The bibliography of J A Vander Linden was first published in 1637, and went through two further editions during his lifetime and one (1686) after his death. It is still used by historians, but the work would be more acceptable now if both Vander Linden and G A Mercklin, his final editor, had adopted Sir Thomas Bodley's request to the first librarian of the Bodleian "I did alwaies wishe that in the setting downe of an author's title, you would place his surname first". The "Bibliotheca realis medica" (1679) of Martin Lipenius contained about twice the number of entries in Vander Linden. It was printed on a quarto page in double column and was, to our eyes, of a much more modern lay-out.

The late eighteenth and the first half of the nineteenth centuries were the age of the great bibliographies compiled by single individuals. Some of these dealt with limited periods and are not discussed by Miss Brodman. Of these may be mentioned Choulant's "Handbuch der Bucherkunde" (1841), which is still of great value. The great bibliographies of this period were undoubtedly those of Albrecht von Haller, of Ploucquet and of Callisen. Haller's bibliography of practical medicine was only one of four similar works which he compiled. It contains fifty-two thousand references to books, dissertations and also to important articles, and it frequently gives brief critical notes on the contents of the works listed. This work by Haller is not of great value to-day, but his "Bibliotheca anatomica" is still a very useful and accurate work. Wilhelm Gottfried Ploucquet was the first bibliographer who had to tackle seriously the problem which is still fundamental—the listing of the journal-article. Between 1793 and 1797 he published eight volumes of his "Initia". The work was then complete—but only to 1793. In the interval new literature had appeared so fast that it required a supplement of four volumes to cover it. Faced then with a further large accumulation of titles, Ploucquet took the bold step of deciding to reprint his twelve volumes in a more complete and convenient format, and to integrate them so as to include their contents and his last accumulation in one alphabet. In this work he had to face the fact that it was no longer possible for one individual to define the contents of all articles listed except from the information given in their titles, and he also realized that important medical observations might be found in works which were not entirely, or even primarily, of a medical character. Callisen's invaluable "Lexicon", published in thirty-three small volumes between 1830 and 1845, is more limited in scope since it deals only with literature published roughly between 1750 and 1830. Ploucquet's work was arranged by subjects, Callisen's by authors' names.

Scientific and medical bibliography now passed into the co-operative stage, the first result being the "Catalogue of Scientific Papers, 1800–1863", which was published by the Royal Society in six volumes in 1867 and the following years. Two new volumes, covering the period 1864–73, appeared fairly soon, but the four additional volumes bringing the work up to 1883 were not published until 1902. For the seventeen years 1884–1900 seven volumes were required, and it took more than ten years to publish them. While the earlier volumes are within the means of the serious historical student, the later volumes are very costly. No supplements have yet been published dealing with the literature since 1900.

An even greater co-operative undertaking is one known to all workers in the medical field, the "Index-Catalogue of the Surgeon-General's Library". There had been five small catalogues of the books in this very rapidly expanding library between 1863 and 1873, when John Shaw Billings conceived the idea of a catalogue which would be arranged by authors and by subjects and which would, in addition, list all the important articles in journals. The first volume was published in 1880 and the sixteenth and final one in 1895. By this time the accumulation of fifteen years, which was to be published in a second series under a new alphabet, had reached such proportions that it took more than twenty years to publish the necessary twenty-one volumes. By 1916, therefore, before the commencement of publication of the third series, all references relating to authors or subjects beginning with the letter *A* were complete only up to the year 1895. From the aspect of current medical and scientific work, the catalogue was generally about twenty years out of date. The third series followed, and then a fourth, which was carried to the first part of letter *M*, when publication stopped with Vol. 10. A final volume is expected soon, but that will probably be the end of this great work.

Of the 178 pages of text in her book, Miss Brodman devotes more than forty to the position at the present day—the varying fortunes of the "Index medicus" and its gradual replacement by the "Quarterly Cumulative Index Medicus", the rise of the "Current List of Medical Literature" and its merits compared with those of its older contemporary. As her work is essentially a history, it may be argued that it would have been better to have stopped at an earlier period. On the other hand, it is desirable that the ramifications of these difficult problems should be fully understood by all who have to make extensive use of medical books and journals, and this final chapter sets out the facts very impartially.

What are the facts ? Long known to all who have viewed the field in historical perspective, they are quite clearly that medical bibliography is not now, and never has been, completely comprehensive and up to date. The early bibliographies were essentially tools for the use of the compilers, and no doubt personal interests sometimes had an effect on their completeness in certain directions. But apart altogether from this factor, there was no chance of a single individual being able to trace all the works published even during a limited period. It has been estimated—admittedly by methods which cannot be very refined—that the number of medical works printed before 1501 was 966, and that between that year and 1636 the number of editions of medical works printed was about twenty-five thousand. In his bibliography, published in 1679, Lipenius lists about 40 per cent of the authors possibly represented by these works. At the end of the eighteenth century Ploucquet was finding that his new material amounted to about ten thousand references a year. Medical and scientific journals were then in their infancy. In 1800 their number was 910. By 1866 it was more than fourteen thousand, by 1901 the number was nearly sixty thousand, and by 1908 more than seventy thousand distinct journals were being published.

Dr. Claudius F. Mayer, the distinguished editor of the "Index-Catalogue", has said that the manuscript cards increase by more than a hundred and twenty thousand yearly. The fifty-seven volumes of the "Index-Catalogue" which have so far been published contain about three and a half million references. Allowing something more than sixty thousand references per volume of the "Index-Catalogue", this means that at least two volumes per year would be required to keep up with the current intake; at its best times only one volume was published per year in the past. The present situation is far from satisfactory, and it may have to be admitted that it is impossible to provide a fairly full bibliography of medicine which is always up to date and which in the same form provides easy reference over a long period. When the "Index-Catalogue" was about to expire, many sincere requests for its continuation passed from Great Britain to the United States, but other considerations prevailed. Despite its faults, the "Index-Catalogue" does provide a permanent record of most of what is worth while, and it does so in a manner which allows of easy consultation.

Miss Brodman has written a valuable little book, to which is appended a very full list of medical bibliographies since 1500. A few minor errors are unimportant; but there is one strange mistake which should be corrected at the earliest opportunity. The author describes the lay-out of a page of Haller's "Primae lineae physiologiae" which she says appeared in eight volumes. The "Primae lineae" was a very fine one-volume students' text-book which went through many editions and translations. The great eight-volume work for which this name is a *lapsus calami* was his "Elementa physiologiae corporis humani", the eight volumes of which were published between 1757 and 1766, and not in 1747 (the date of the first edition of the shorter work). Miss Brodman perhaps gives the impression that the *Philosophical Transactions of the Royal Society* was a private venture only during the time of Oldenburg. In fact, the journal was the property of the secretaries of the Royal Society until the year after the death of Sloane. Apart from a reference in the appendix, she makes no mention of Pauly's bibliography of 1874. This is not an important omission; but in view of the fact that this work has recently been reproduced in facsimile—some authorities may consider the reproduction was uncalled for—a few notes on its merits might have been useful.

E. Ashworth Underwood

A TECHNOLOGICAL APPROACH TO THE STUDY OF BACTERIAL MORPHOLOGY

La Cellula Batterica

Di Dr. Franco Scanga. Pp. xix+477. (Roma: Il Pensiero Scientifico, 1954.) 8000 lire.

THE recent very considerable advances which have been made in the study of the morphology and cytology of bacteria have been published almost exclusively in English. It is therefore something of a landmark in the history of the subject to find so well-informed a work in any other language; and it says much for the excellence of Dr. F. Scanga's handling of his material, and the clarity of his Italian style, that I was able to read an extensive passage from one of my own works, translated from English, without any feeling of unfamiliarity. This is not always true of paraphrases in the same language by other pens.

The book is in no sense a monographic study, but is rather an attempt to provide a fully documented account of recent work in this field, with an almost exclusive emphasis upon the better-known groups of bacteria. Although the effect has been to make it considerably larger, and thus presumably more expensive, than would otherwise have been necessary to convey the essential information, the language problem dictates that this is much the most valuable, and indeed the only suitable, form for the book to take. For example, Dr. Scanga neither supports nor opposes the claims of the Philadelphia group, but simply states them at length and follows with an equally full quotation from one of their more outspoken critics. The reader is left to form his own opinions.

The illustrations are numerous and well reproduced. Full use has been made of the plates which originally appeared in the Symposium on Bacterial Cytology, held in Rome in 1953, but not always with the happiest results, since many of these were originally provided by the contributors to illustrate particular points rather than general principles. It is especially unfortunate that the caption of Chapman and Hillier's now famous electron micrograph of a section of *Bacillus cereus* gives an interpretation proposed by another person on that occasion, rather than the entirely different, and much more generally acceptable, interpretation of the original authors.

As may be expected in a book of this nature, technical questions are given great prominence, and a wide selection of cytological methods is described in full, with the originators' own opinions in respect of their efficacy stated without comment—a state of affairs which may mislead intending practitioners, in some cases. Dr. Scanga's own special interest is the electron microscope, which he handles with considerable skill; and a valuable account of the techniques accompanying the use of this instrument is included. Electron micrographs accordingly provide a somewhat disproportionate preponderance of the illustrations. It might, in other circumstances, be regarded as slightly curious that the only really clear example of the now classical appearance of the bacterial nucleus, by the Robinow–Piekarski technique, is included in a page of electron micrographs, in order to establish that the much less instructive protuberances, visible upon these desiccated surfaces, actually represent the nucleus.

But these are minor blemishes in an otherwise excellent work. The author has taken the trouble to acquaint himself with the massive body of evidence which has become available, at least within the limits which he has set himself, and shows every sign of understanding it thoroughly. This is especially refreshing in a field where many who have started out with similar high intentions have retired before long behind a smoke-screen of obscurantism.

COLOUR PHOTOGRAPHY

Principles of Colour Photography

By Ralph M. Evans, W. T. Hanson, Jr., and W. Lyle Brewer. Pp. xi+709. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 88s. net.

SOME readers of this authoritative book are likely to be disappointed unless they appreciate that it is the principles of colour photography which form its subject-matter and not colour photography itself. Only one chapter of forty-one pages out of a total of more than seven hundred is devoted to a description of the various colour photographic processes and cameras, and no colour prints are included anywhere in the book. Readers must therefore go elsewhere for a colourful presentation of the subject; but they need be under no illusion as to the ability of the authors to practise the art about which they write, for one of them, R. M. Evans, is perhaps the outstanding exponent at the present time of the artistic possibilities of colour photography.

The theory behind colour reproduction, whether by photography or television, has become quite highly developed, and the starting point is usually the laws of three-colour mixture. In terms of colorimetry, the reproduction should consist of the appropriate combination of red, green and blue radiations that will, at each point of the picture, match the colour of the original at that point This provides a working hypothesis from which to derive such items as the theoretical spectral sensitivities of the three light-sensitive processes in the colour camera For various reasons, major departures from colorimetric theory are both necessary and inevitable, and it is no easy matter to present a comprehensive and comprehensible account of all the factors that ultimately have to be considered This, however, is in essence the main intention of the book under review and the authors have made a notable and successful contribution in this field

First, we have chapters dealing with colour matching and colour measurement (those interested in the algebraic representation of these matters will be surprised to find colour equations given in a form which has been generally condemned in the United States although common practice in Great Britain until recently), followed by a discussion of the visual processes of adaptation, contrast and the like, which affect so vitally the subjective appearance of a picture yet are so baffling to express in algebraic or numerical terms Next, we have chapters on the chemistry of the photographic processes and the optical characteristics of dye mixtures and their measurement, leading naturally to colour sensitometry and the consideration of the *H* and *D* characteristics of colour processes Two chapters dealing with the special cases of duplicating and copying are interpolated, and the final two chapters discuss the generalized theories of additive and subtractive reproduction

It will be realized that this book is full of weighty material which cannot be described as light reading, yet the text itself is written in a very clear style and is therefore easy to read The authors are well aware that they have not written the final word on the subject, for their closing paragraphs and indeed the closing sentence emphasize that lack of knowledge of the visual relationship between the photograph and the scene makes it necessary for present-day processes to be worked out empirically. Yet this is an excellent statement of our present understanding of the problem, and no serious workers in colour photography or colour television can afford to ignore it if they wish to reduce the empiricism in their techniques to a minimum

W D WRIGHT

PRESENTING MODERN CHEMISTRY

General Chemistry

An Introduction to Descriptive Chemistry and Modern Chemical Theory By Prof Linus Pauling Second edition Pp xii+710+2 plates (San Francisco W H Freeman and Company, 1953) 6 dollars , 51*s*

WHEN, at a conference in the United States, Prof Linus Pauling was asked about his views on the teaching of chemistry he is reported to have said "One wants to teach that section which inspires and holds a man and which feels alive , then, moving on to greater and greater triumphs, that which both fascinates and profits mankind The text-book should contain what the writer really believes and really knows, not the stuff which seems dead and ought to be put into museums". The speech reveals the attitude to teaching in which "General Chemistry" was written and the principles which guided the writer in selecting his material and arranging its sequence "That which inspires and holds a man . .” the speaker, the grand-master in the field of the ionic bond and of the electronic structure of the molecule, showed in this work how a simple exposition of modern theoretical concepts could, to use his own words, make the presentation of general chemistry "more simple, straightforward and logical than formerly" All who have used modern theory in their teaching will concur "General Chemistry" rapidly obtained world-wide recognition as belonging to that small class of books, as did the works of W Ostwald and of Alexander Smith in days gone by, which revolutionized the teaching practice then prevailing and laid down the pattern for future texts

The first edition was reviewed and commended in *Nature* (June 26, 1948) its contents are too well known to be again listed , but those yet unacquainted with "General Chemistry" should know that it is an introduction for first-year university students In this, the second edition, Prof Pauling gives us further teaching help, for he shows us how he meets the difficult problem of giving an adequate presentation of a science, which, already huge, is expanding in every direction His plan is to increase the depth of the treatment of theory, especially of those aspects which are pertinent to the explanation of chemical behaviour and which are integrating in their incidence, so that all but the future specialist will have sufficient theory to carry him through his entire chemistry course At the same time, a new chapter entitled "Biochemistry" extends the breadth of treatment and introduces a humanizing factor For this chapter is essentially a fascinating essay on proteins, vitamins, drugs and their relation to life and mankind

Most of the additional theory is in two new chapters, respectively entitled "The Electron and the Nucleus", and "Quantum Theory and Molecular Structure". Among the topics discussed in these chapters are X-rays, the electron, radioactivity, the atomic nucleus, the quantum theory, the photoelectric effect, the photon, and the changed outlook brought about by quantum mechanics

The new introductory chapter on metals is not only interesting and inspiring but also illustrates the author's ability to use the electronic theory to explain and systematize the phenomena under discussion Thus he shows how the increase in the structural strength of successive metals in a Mendeléeff period is dependent upon the electronic configuration of the metal and of the arrangement of its atoms in the crystal Physical properties are therefore no longer seen as haphazard phenomena but, as with chemical properties, are determined by structure, and are predictable

The four new chapters, and the revision and frequent extensions of most of the original chapters, enlarge the book by 115 pages The flashes of understanding which must come from a study of "General Chemistry" and the freshness of approach to the subject-matter make it an excellent text for first-year university students or for candidates for university scholarships If not used as a text-book, a copy should be in every chemical library.

G. FOWLES

THE UNIVERSITY OF MALAYA

By SIR SYDNEY CAINE, K.C.M G.

Vice-Chancellor

THE University of Malaya is now five years old What are its achievements, its opportunities and its problems ? Created by the amalgamation of two Singapore institutions, the King Edward VII College of Medicine and Raffles College (covering arts and science), its first tasks were to merge these two units and secure recognition of their standards , to extend the range of teaching , to get assured finance for maintenance and growth , and to create an adequate physical centre for itself

During all its early years the University has been troubled—some would say bedevilled—by the last problem, of siting. It had been agreed by the Governments of Singapore and the Federation of Malaya that the University should be moved out of Singapore to a site some twenty miles away in Federation territory, across the Strait of Johore This project had many attractions, especially politically , but as time passed it became very clear that such a move would meet many obstacles, would cost vast sums of money and would take many years Doubts accumulated of the inherent wisdom of removing from close contact with the life and culture of the leading city of Malaya Growth in numbers—much more rapid than had been expected—produced pressing demands for more facilities now on the Singapore site rather than alternative facilities years hence elsewhere , but action was paralysed by the prospect of ultimate removal.

The financial position was equally inimical to long-term planning. The two Governments had met without demur the annual demands of the University as presented but had made no specific promises for the future as to either recurrent or capital expenses, leaving the academic staff in doubt whether money would always be forthcoming so readily and so unconditionally.

During the past year both site and finance have been publicly discussed and reviewed by the University and the Governments Three main conclusions have been unanimously accepted the project of removal to Johore is abandoned , the University will retain its home in Singapore where it has considerable space for development, but will also, with growth in student numbers and in technical studies in mind, begin a second university centre at Kuala Lumpur, the Federation capital , and finance is assured by a promise of annual Government grants over a five-year period on an escalator basis, plus a minimum capital grant. The money promised is less than the University asked for , but the minimum annual grant is to rise from £640,000 for 1954–55 (against £560,000 in 1953–54) to £780,000 in 1958–59 For capital the University will be largely dependent on further assistance from the Colonial Development and Welfare Fund (from which £1,000,000 is already promised) and from private benefactions These decisions give a firm basis for further progress, and urgently needed new buildings will be started almost at once.

What, on the other side, is the academic basis for progress ? The existing faculties are in arts (including English, oriental studies, geography, history, economics, education and mathematics), science and medicine, making a total of twenty-seven departments Staff has expanded from the 60 taken over from the Colleges to 140 at the beginning of the 1954–55 session Student numbers have grown in five years from 450 to 1,050. New departments added since 1948 include education, Malay studies, Chinese language and literature, philosophy, social medicine, parasitology and orthopædic surgery Social studies, in which a diploma is awarded, has been added as a sub-department of economics, and independent lectureships have been established in the history of art and in child health Although additional buildings are needed, the University is already fortunate in having good and well-equipped laboratories, a large and progressive teaching hospital and substantial general accommodation. By a wise decision, the one important building put up since 1949 has been a well-equipped library which houses a good collection of English books and one of the largest collections of Chinese books in Asia outside China itself.

In maintaining degree standards, the University relies very much on the distinguished scholars from the United Kingdom and elsewhere who act as external examiners and pay regular visits Its M B , B S., like the medical diploma of the former College, is a registrable qualification in the United Kingdom and, more significantly for the reputation of the Medical School, the Malayan diploma in public health begun last year was at once recognized by the General Medical Council. No equally clear-cut 'recognition' is available for non-medical degrees , but students with a University of Malaya honours degree are accepted for higher studies at leading universities and professional institutions elsewhere

Academic standing is judged not only by the first degrees awarded but also by the output of research Here, after five years, it is fair to look at the promise rather than the achievement Recognizing the importance of research, the University immediately provided for a full range of higher degrees To date it has awarded seventeen M A s or M Sc s, three Ph.D s and five M.D s At the commencement of the 1954–55 session, twenty-seven students were registered for higher degrees Much research work is also being pursued by senior members of the staff without formal registration, and there is a steady flow of papers published in learned journals A research unit for social research has been set up, and several research students have been attached under Fulbright arrangements

The University is thus a functioning mechanism, sending a regular stream of graduates into the professions and public services of Malaya—some 70 doctors and dentists a year and 120 non-medical graduates , and prosecuting specific research in all its main branches of study. What are its opportunities ?

First are its teaching opportunities Malaya is progressing steadily towards self-government , the senior Government services, the professions and local business managements will soon be recruiting scarcely any but local men and women They need not all be locally educated , but the University of Malaya ought certainly to provide a high percentage of the university-trained personnel of the Malaya of the future To do that it must broaden the scope of its teaching It must add departments or faculties in engineering, agriculture, law and the complex group of social studies which includes government and political science, applied economics and social anthropology A start is to be made on all these within the next quinquennium, besides developing existing departments.

Such a widening of scope is not too ambitious if full university stature is to be attained, and there is adequate reason to expect a flow of students sufficient to fill these courses and, incidentally, to justify the beginning of university teaching in Kuala Lumpur There are to-day more Malayan young men and women studying at university-level outside the country than there are at the University of Malaya, most of them are studying subjects not yet taught in Malaya, and a good proportion would no doubt have come to Singapore if these subjects had been offered there Furthermore, a very rapid expansion in secondary education is taking place in Malaya. Even allowing for some brake on expansion at the higher levels imposed by shortage of teachers capable of maintaining the necessary standards, the numbers seeking a university education look like doubling in the next decade

Relevant to the question of numbers is the fact that the University to-day draws very little upon the 'Chinese' schools, which provide a self-contained system of primary and secondary education distinct from the 'English' schools and relying mainly on Chinese as a medium of instruction and on Chinese inspiration in general subjects Pupils from such schools qualified for a university education formerly went to China for it There is now a project to create for them a separate institution, to be called the Nanyang University, although they are only a fraction of those from the English schools and could scarcely support a separate university of Western academic standards It is important that they should not be denied entry to the University of Malaya, and means are now being examined by which the language difficulty can be surmounted and a regular channel of entry from these schools established

A university is not, however, just a machine for turning out highly trained professional men Equally important are the spirit, the philosophy and the culture they carry with them. Here the prospective political and social development of the country makes the role of the university even more vital Maintaining the values of life as we see them in the West, and the standards of political and public life, will make great calls on the young men and women who will be filling the public services, the law and other professions in the next five or ten years In living up to its responsibilities in this field, the University has to steer a delicate course in the teaching, encouragement or toleration of political thought and discussion, still more delicate are the susceptibilities in the religious field when students are drawn from so many faiths—Moslem, Confucian, Hindu, Buddhist and Christian In so far as political, philosophical or religious ideas are taught, they tend to become vague distillations of the essential truths of many creeds and to lack sharpness and punch The widely realized problem of how to instil some real philosophy of life in a secular university is particularly difficult in a country of such varied make-up and in which almost all identifiably Western doctrines except Communism are liable to be suspected of a 'Colonial' taint None the less, difficult as the task is, the handing on of the essence of Western culture is one of the greatest of the opportunities of the University of Malaya

So much for what can be taught What of the things to be learned, the research opportunities? In natural science special opportunities arise from the physical situation of Malaya Singapore is barely 1° from the Equator In physics, although claiming no special facilities for pursuing the main lines of current physical research, Singapore is uniquely situated for the study of equatorial meteorology, Malaya can also offer its own special contribution in rock magnetism Probably no other university offers as good facilities for the study of equatorial marine fauna In botany there is the basic study of the behaviour of plants in a virtually seasonless climate, as well as much scope for further systematic work on the rich equatorial flora, and chemistry can, *inter alia*, supplement the work of the botanist with systematic study of the properties of that flora

The geographical situation also opens opportunities of special research in the medical field The distinguished tradition of research in Malaya is still carried on in the Institute for Medical Research at Kuala Lumpur, and is now being supplemented by work in the University Among many special topics attention is being paid to parasitology, local virus diseases and to physiological reactions to the heat conditions of the equatorial tropics

In human or sociological studies, special opportunities arise less from the equatorial situation than from history and economics South-east Asia has always been a meeting-place of cultures, and the ordinary complications of mixed societies are given a special flavour in Malaya by the fact that the diverse races are mixed in such proportions that each one is, statistically speaking, a 'minority'. The very newness of the country—by the standard of the date of effective opening-up to close human settlement most of it is newer than the United States—makes its sociology a living study of pioneering and of the absorption of mass immigration In economics, Malaya provides an outstanding case of the 'export economy' and of dependence on highly fluctuating world markets, and much of the special reaction on the local economy has still been only superficially studied As background to all this, more complete study of the history and geography of both Malaya itself and the surrounding countries is being systematically tackled by enthusiastic teams in the respective University departments In all fields the geographical situation and communication facilities of Singapore justify hopes of its becoming a major centre for the study of South-east Asia as a whole

A third field of opportunity for the University lies in extra-mural work in a much wider sense than usual, implying not merely (indeed scarcely at all) formal teaching outside the University's walls but also encouraging, stimulating and assisting whatever local initiatives develop in the fields of art, music, literature and general study. Already the University is establishing itself in this way as one of the centres where the public may hear good music, watch plays or look at exhibitions of visual art, and as the headquarters or inspiration of national societies such as the Malayan Historical, Science or Mathematical Societies

Lastly, what are the problems of such a university? One major problem already mentioned—how to influence the souls and the philosophical beliefs of its students as well as their minds and their technical knowledge—is bound up with the way the students live. To-day the University of Singapore is more like a British civic university than one of the ancient universities; true, a high proportion live in university residences, but those residences are properly called hostels rather than colleges and have scarcely any of the collegiate atmosphere. The development of that depends on physical facts and will necessitate extensive new building. A second problem is the recruitment of staff. Naturally it is the aim to recruit locally as much as possible, and more than 40 per cent of the staff (including five heads of departments) are Asian; but extensive reliance will be placed for many years on outside recruitment. To-day the non-locals are themselves a very mixed group, countries of origin including, besides the United Kingdom, every other nation in the Commonwealth, Ireland, the United States, Denmark, Sweden, the Netherlands, Switzerland, Germany, Austria, Czechoslovakia, China, Indonesia and Thailand. This diversity of origin broadens the University's scope, but adds to the problems of spiritual unity. The determination to attract staff of the right quality is shown by the very high salaries and allowances offered (for example, assistant lecturers starting at £1,490 per annum actual emoluments and lecturers ranging from £1,638 to £2,688).

Recruitment is linked with a third general problem—the danger of isolation. The fear of being cut off from the intellectual stream of the big universities undoubtedly deters many potential recruits and is a danger in the wider sense to a university the nearest Commonwealth neighbours of which, Hong Kong, Ceylon and Western Australia, are all more than 1,500 miles away. The University reduces the isolation by generous vacation and study leave, by the external examiner system and by seizing every opportunity of attracting distinguished visitors, who can often be caught in Singapore almost literally on the wing as they fly through *en route* to Australia or the Far East. None the less, the maintenance of contacts with Commonwealth, American and European universities is a constant problem, in the solution of which every possible outside help and sympathy are needed. The recent institution of scholarships for the children of United Kingdom staff of Colonial universities by Birmingham is an example of the sympathetic interest required.

Space does not permit of discussing here more localized problems—the administrative complexities of development in Kuala Lumpur as well as Singapore, the linguistic problem of teaching in English to students of diverse mother-tongues, the problems of school educational standards, etc.—but something must be said about costs. All the growing Colonial universities cost a good deal more per student than the average United Kingdom or Commonwealth university. Apart from the inevitable burden of overheads in small institutions, salaries have to be much higher to attract staff, passage and leave grants are expensive and the expenses of external examiners add further to the cost. It must sometimes seem, therefore, as if it would be no more expensive to maintain all the students overseas at older universities. That would be an exaggeration; but in any event this must be regarded as an initial phase of costliness which will pass as more local talent becomes available. The high current costs of operation are properly regarded as part of the capital costs of building up institutions which, in Malaya and elsewhere in the Colonial Empire, represent one of the greatest, if one of the latest, of the contributions of Western influence to the full growth and development of these territories. No better use can be found for further United Kingdom assistance to Colonial development and welfare than a continuance of the generous grants which have made possible the initiation of these overseas university institutions.

RECENT TRENDS OF GLACIER FLUCTUATIONS IN THE NORTH ATLANTIC AREA

A LARGE and varied audience attended a discussion on "Recent Trends of Glacier Fluctuations in the North Atlantic Area" held by the British Glaciological Society in the Department of Geology, Oxford, on November 19. This was the first meeting of the Society to be held in Oxford for some years, and it was opened by Mr. G. Seligman, president of the Society. The main part of the meeting took the form of five short papers given by Mr. C. W. M. Swithinbank (Pembroke College, Oxford), Dr. C. A. M. King (Department of Geography, Nottingham), Dr. M. M. Sweeting (St. Hugh's College, Oxford), Mr. M. F. W. Holland (St. Peter's Hall, Oxford), and Mr. H. Lister (Department of Geography, Cambridge). These papers were mainly concerned with the results derived from recent field-studies on glacier regime and fluctuations in areas around the North Atlantic, particular attention being paid to fluctuations during the past fifteen to twenty years. Prof. Gordon Manley (Bedford College, London) attempted the difficult task of summing up the very diverse contributions and of assessing the extent of the dependence of glacial variations upon present climatic developments. Dr. K. Sandford (Department of Geology, Oxford) was in the chair.

In the first paper, Mr. Swithinbank reviewed the latest work in Scandinavia, where practically every glacier has been in retreat for more than half a century. The rate of retreat increased during the 1930's and caused the disappearance of several small glaciers. The changes of the past ten to fifteen years did not, so far as can be seen at present, reflect either a significant increase or decrease in the prevailing high rate of retreat. We are hampered in a study of recent trends by the small number and indifferent quality of available measurements. A change in the 'state of health' of a glacier is best defined in terms of changing total ice volume and changing material balance. Accumulation and ablation measurements have been made since 1945 on one glacier in western Norway (Storbreen, Jotunheimen), and one in Swedish Lapland (Storglaciaren, Kebnekajse)[1]. The marginal retreat of these two glaciers has not, however, been proportional in single years to the net deficit of their regime. Mr. Swithinbank was therefore distrustful of measurements which referred only to the snout recession of Scandinavian glaciers.

Though most glaciers show a time-lag of several years in their response to climatic change, and some appear to follow a rhythmical advance and retreat that is largely independent of short-period fluctuations, there is in Norway a fairly good correlation between the trend of annual mean air temperatures and the mean rate of recession of the glaciers. While the present glacier trend in western Norway is mainly due to a steady increase in the length of the ablation season, in Swedish Lapland it is apparently caused by rising summer temperatures, which have led to greater rates of melting during the mid-summer months In west, though not in north, Norway there has been also a steadily decreasing winter accumulation This is noteworthy, as it contrasts with a more general trend of increasing precipitation recorded at most of the low-lying meteorological stations in the country

Mr Swithinbank thought that conclusions of great interest are to be expected in a few years time, when we shall be able to compare running means of the yearly volume changes of a number of glaciers with running mean figures of the climatic elements obtained from observations on the glaciers themselves, rather than at places (like most existing stations) which differ from the glacier-covered areas both in altitude and exposure

The subsequent papers dealt with details of glacier fluctuations based on field-studies made in the past few years Dr King discussed the fluctuations of four glaciers draining south from the ice-cap of Vatnajokull in Iceland She said that the evidence included measurements of the glacier snouts carried out since 1932 and also evidence of thinning and retreat from field observations made in 1953 and 1954 The following figures give the long-term and more recent trends

Glacier	1932–53	1951–53
E Skeidararjokull	– 460 m	– 34 m
Morsarjokull	– 557 m	– 33 m
N Skaptafellsjokull	– 800 m	+ 24 m
S Skaptafellsjokull		– 8 m
N Svinafellsjokull	– 540 m	+ 14 5 m
S Svinafellsjokull	– 136 m	+ 13 5 m

These figures show that on Skaptafellsjokull and Svinafellsjokull the retreat is slowing down or reversing, while the other two glaciers continue their rapid retreat S Svinafellsjokull has scarcely retreated at all during the past ten years These observations may be accounted for by the variations in height of the accumulation areas of the glaciers concerned, as shown by the following figures

Glacier	Accumulation area (per cent) above 1,400 m	Accumulation area (per cent) above 1,700 m
Morsarjokull	0	0
Skaptafellsjokull	22	8
Svinafellsjokull	51	22

The evidence of thinning of the glaciers indicates a very substantial loss of volume Morsarjokull has thinned by 90 m since 1904, during this period two of its three tributaries have become disconnected Skeidararjokull during the same period has thinned about 76 m on the evidence of a well-marked trim line Skaptafellsjokull and Svinafellsjokull were joined at their snouts until the rapid retreat caused their separation in 1935 Since this time Skaptafellsjokull has retreated and thinned rapidly, but Svinafellsjokull, particularly at its south end, has stagnated The glacier has, however, thinned by 60 m. recently, as indicated by a very pronounced trim line at this height

The variability of accumulation is marked, which causes considerable variations in glacier budget and fluctuations from glacier to glacier and from year to year Dr. King concluded that the evidence indicated in general a rapid retreat and thinning of the outlet glaciers of S W Vatnajokull, with some exceptions. Those glaciers with the highest accumulation areas are advancing slightly at present

Dr Sweeting gave evidence for recent glacier fluctuations in Spitsbergen, where the glacial recession has been very rapid since 1890 She discussed details recorded by Miss G E Groom and herself in 1953 of the state of the glaciers in Bunsow Land, central Vestspitsbergen In this area the disintegration and thinning of the plateau glaciers have continued, apparently unabated, in the past twenty years Many small glaciers mapped by the Cambridge Spitsbergen Expedition in 1938 have now disappeared All the glaciers examined in Bunsow Land in 1953 showed signs of marked recession Great heaps of moraine now remain in front of gently sloping glacier snouts, in many places the ice is stagnating at its terminal ends Dr Sweeting quoted as an example, in Bjonadalen, in south-east Bunsow Land, a simple confluence system of two glaciers, the long confluent snout of which has become stagnant, this stagnant ice-mass is in process of being severed from its feed glaciers and is becoming a dead-ice patch Dead-ice accumulations were mapped in other valleys in Bunsow Land where the glaciers have retreated to leave only a much attenuated snout in the valley head Some of the steeply inclined cirque-like glaciers have also become detached from their supply areas and are now dead ice.

The behaviour of the major ice fronts in Bunsow Land has been studied since before 1900. The ice front, still largely afloat, of the Nordenskjold glacier has been mapped by a series of Cambridge expeditions since 1938 Between 1938 and 1953 it showed a continuation of the retreat which was so marked a feature of the 1920's and early 1930's, during 1938–49 the retreat averaged 6–15 ft a year[2]

No detailed observations on accumulation and ablation have yet been made in this part of Spitsbergen, but the rate of ablation in 1953 was undoubtedly high. In the last weeks of July and the first weeks of August, during the height of the ablation season, the rate of ablation at 500 m was approximately 29 mm per day

Glacier recession has been less marked in North East Land, an island lying to the north-east of the main island of Vestspitsbergen, which is both much more ice-covered and more 'polar' in character Mr Holland said that recent observations in North East Land tended to confirm the view held by Glen that the ice is in a generally passive state and that it has a negative regime In the southern part of the island there is evidence of wastage of the ice in the presence of high heaps of glacio-fluvial debris and in the tendency for small glaciers to become detached from the main ice-caps The outpouring into the sea of the large ice lobe of Bråsvellbreen from the ice cap of Sorfonna in about 1937 was a spectacular example of the advance of a glacier which probably bore no relation to the present glacial balance and was not an indication of increasing glaciation[3] Mr Holland discussed the possible causes for this advance

The problems concerning glacier fluctuations and regime clearly become more difficult the larger the ice-mass, we have also very little information about the world's large ice-caps These points were stressed by Mr. Lister, recently back from the British North Greenland Expedition Conclusions drawn from a study of the advances and retreats of the glaciers associated with the Greenland ice-cap are likely to be misleading, and the fluctuations of the glaciers in Queen Louise Land do not throw much light upon the glacial balance of the area However, the existence in Queen Louise Land of a well-marked trim line suggests that thinning of the ice there has occurred Preliminary results also suggest that in this part of North Greenland ablation at present exceeds accumulation and that there is a negative balance The recession of the glaciers up the fjords is fairly well established, thinning is not so marked but a new nunatak had appeared[4] There has been a general decline in the accumulation of inland ice, but recent years have shown a slight increase

It has been said that the "intensity of glacial recession and shrinkage in recent decades round the northernmost Atlantic constitutes perhaps the clearest indication, among many, of a climatic fluctuation in this region"[5]. The rise of temperature in the northern hemisphere has reached its maximum value in Vestspitsbergen, where the shipping season has lengthened from three months at the beginning of the century to about seven months in the 1940's[6] Investigations into the causes of glacier fluctuations are therefore of more than glaciological interest It was along these lines that Prof Manley summed up the evidence of the five principal speakers With regard to Mr Swithinbank's remarks, he agreed that each glacier must be treated on its own merits Yet if the aggregate effect on the movement of the firn-line, for example, is taken over a decade and for, say, a score of glaciers, as in Iceland or Switzerland, the evidence for temperature trend is undeniable, further, it is supported by actual instrumental data To Prof. Manley, the fundamental factor linking these varied field investigations around the North Atlantic is that of climate and especially the mean summer temperature He showed the extent of the correspondence between the fluctuations of glaciers and the overall variations since 1700 of the accumulated summer temperatures on British uplands[7]. It was also noteworthy that the accumulated temperatures of the summer months, corresponding with the ablation season on glaciers, varied in much the same way in eastern North America

Other problems of glaciological research, Prof Manley pointed out, had also been raised At what stage did a snow-bed become a glacier ? The small remnants of ice that had been shown in the heads of steep gullies in Spitsbergen begged the question of why cirques had not developed in that area Field-investigation of glacier behaviour is strenuous and it is necessary to accumulate and integrate results before conclusions can be reached Glacier fluctuation in Spitsbergen, and probably also in North-East Greenland, is closely connected with the behaviour of the ocean waters and the extent to which sea ice is formed Ultimately, it will require the collective efforts of many sciences to solve the major riddle, that of ice ages, but field-work will provide the foundation The field-study of glaciers, like all other field-studies, opens up a variety of further problems for others to discuss

Speakers in the later part of the discussion were much exercised with the causal connexion between the recent glacial fluctuations and the present climatic developments Prof H W Ahlmann has already pointed out that the present climatic improvement probably culminated during the 1930's and 1940's, and that in North America the decade 1941–50 was characterized by somewhat lower temperatures and increased precipitation compared with the decade 1931–40[6] The most important factor so far in causing the recession of the glaciers in areas around the north Atlantic has almost certainly been the greatly increased ablation But as Prof. Manley pointed out, a series of wet cool summers like the one we have had in 1954 might well alter the ratio of accumulation to ablation and cause a reversal of the present trend of glacier fluctuations, hence, climatic developments of the near future are of particular significance

BRITISH COTTON INDUSTRY RESEARCH ASSOCIATION

ANNUAL GENERAL MEETING

THE thirty-fifth annual general meeting of the British Cotton Industry Research Association was held at the Shirley Institute on Thursday, December 9, the chairman of the Association, Mr. N. G McCulloch, presided In his address he referred to the importance of the long and valuable experience acquired by the Institute over thirty-five years, but he also pointed to the need for periodic reviews of policy in order that the Association should continue to pursue the correct objectives He was particularly concerned with the problems of developing research results and the financing of such development, and with the continued need for close liaison between Institute and mill, in which he thought the trade associations can play a considerable part The honorary treasurer of the Association, Mr J Lindley, reviewed the statement of accounts for the year, and reported that the introduction of the statutory levy has resulted in a considerable increase in the stability of the Association's finances He warned members, however, that, particularly as a result of continuing inflation. but also because of the increasing demands being made by members, increased expenditure in the future was unavoidable

Dr F C Toy, director of research, presented his annual report, and described the previous year as one of great activity in which the maximum efforts of the staff had been required to meet the demands made upon them by members He made particular reference to the newly joined doubling and condenser spinning members, for whom new programmes of work had been begun Dr Toy referred to the increasing popularity of the 'Shirley' automatic size box (referred to by one member as "the greatest advance ever made in sizing technique"), and directed attention to a natural development from the size box—the new cold-slurry sizing process Another programme of work in its early stages was specially mentioned, namely, a fundamental study of the problems concerned with blending fibres, particularly man-made fibres, with cotton and with each other. Dr Toy pointed out that the Institute now has a staff of four hundred and fifty, and he felt sure that the future is full of promise

The Institute's laboratories were open for inspection for two full days, when the whole of the staff was available for consultation, and thirty special exhibits had been prepared. For spinners, three practical results of the work of the Spinning Department were on view: a new type of delivery box for use in the pneumatic conveyance of cotton, a guide for controlling the arrangement of yarns in manifold threads, and the first part of a miniature spinning plant for use in the mill. For the more scientifically-minded, apparatus was shown which had been designed for the study of factors affecting yarn behaviour during ring-spinning. This physical examination is a complicated one, demanding simultaneous measurement of such factors as balloon shape, yarn tensions and ring friction.

In the Weaving Department sizing was in progress, using the automatic size box fed with cold starch slurries. The use of these slurries is only possible because of the control exercised by the automatic size box, which compensates for viscosity changes that occur as the cold slurry is gelatinized; there is considerable saving in the boiling time required and in the ease of handling the size. The samples of cloth woven from slurry-sized warps were shown to be quite satisfactory. Another exhibit concerned with sizing illustrated the work which is directed towards elucidating the difficulties arising in removing starch, during finishing, from fabrics woven from spun viscose. This work is fundamental and involves studying the effect of the rate of drying on the solubility of size films, and is related to studies of the molecular structure resulting from different drying histories. An exhibit in another department of the Institute showed the results of investigations of several new sizes, which had been examined from the point of view of ease of removal in finishing. In the Weaving Shed there was a demonstration of a pneumatic device designed at the Institute to prevent the defect of 'lashing-in'. This defect arises on certain multi-shuttle looms, when weft running from the fabric to a temporarily inoperative shuttle in the shuttle box is carried into the fabric by the operative shuttle.

In the Finishing Department, considerable interest was aroused by a new experimental raising machine, designed at the Institute to study fundamentally the process of raising, and initially the different types of drive to the raising rollers and their power requirements. Much work has been done in this Department on measuring the areas of contact between mangle and calender bowls, and two simple methods were shown which have been specially designed for works use. The bowl deflexion indicator, for example, measures the deflexion of bowls under load and indicates the amount of camber required to correct for this, and to give regular mangling or calendering along the length of the bowl. Of particular interest to chemists were the results shown of an investigation on the minimum requirements of sodium hydroxide and sodium hydrosulphite for a number of vat dyes in the pad steam-dyeing process.

The Rayon Department at the Institute is concerned with all fibres (other than cotton) which can be processed on cotton-type machinery, including viscose and cellulose acetate, and also nylon, 'Terylene' and other synthetic fibres. An interesting exhibit was that of work which has proceeded for some years on the effect of molecular weight and molecular arrangement on the tensile properties of cellulose acetate monofilaments. Also in the Rayon Department was a demonstration of methods of analysing fibre blends. The development of these techniques was a necessary part of the fibre-blending programme referred to in his address by Dr. Toy. Crease-resistant rayon fabrics are now produced in large quantities, and an attempt is being made to relate the mechanical performance of these fabrics to the physical properties of the fibres and the chemistry of the various processes involved.

The Silk Department at the Institute serves a group of members who, before the War, were concerned almost solely with this fibre. These members have more recently become increasingly interested in modern synthetic fibres, nylon and 'Terylene' in particular. There was a demonstration of an experimental machine designed to investigate the hot-stretching of nylon and 'Terylene'. The Department has done much pioneer fundamental work on the chemical constitution of silk fibroin and sericin, particularly by chromatographic and X-ray analysis, and there was a demonstration of how the chemical constitution of different silk fibroins affects some of their textile properties.

An exhibit of particular importance, and one which aroused great interest, was of thirty-five instruments devised at the Shirley Institute for development work, and particularly for quality control in the mill. Many of these instruments are now manufactured for and sold by Shirley Developments, Ltd., the commercial subsidiary of the Association, recently set up to exploit its inventions. Prototypes of such instruments, and, indeed, all new equipment, large or small, are made in the Institute's Engineering Department, which comprises drawing office and combined engineering and instrument workshop. Examples of the productions of this Department were shown in the shop, including an experimental suction drier for the Finishing Department, and parts of the miniature spinning plant for mill use, mentioned above.

The Institute's work on the elimination of problems in the mill due to static electricity is complete for the time, and there was a display of the various devices which have been produced. This work on the elimination of static has, however, stimulated a more fundamental programme on the mechanism of static production, which physicists were able to discuss with the members of the staff concerned. This work may well be closely connected with the difficult problem of reducing the tendency of textiles to acquire temporary or permanent soiling, and the work of the Institute in this field was demonstrated, and more particularly an apparatus designed to measure atmospheric dirtiness, which has already received considerable use in mills.

There are many empirical instruments and methods in commercial use for assessing the textile properties of fibres, yarn and fabrics, some of them originating in the United States. The policy of the Institute is to examine critically all such instruments and methods and report its views to members. Many of these methods were shown in operation.

The annual general meeting gave members a fuller opportunity of visiting their central research organization than has been afforded since the War. The result was highly satisfactory in that there was a large attendance of more than seven hundred visitors. Members and staff were equally pleased with the success of the occasion—members with the wide range of the work proceeding, and the staff with the interest shown by the visitors and the extent to which their work was understood and appreciated.

OBITUARIES

Sir Arthur Keith, F.R.S.

With the death of Arthur Keith on January 7, there has passed one of the most outstanding exponents in his time of human and comparative anatomy and of physical anthropology.

Arthur Keith, the son of an Aberdeenshire farmer, John Keith, was born in 1866. In 1884 he entered Marischal College as a medical student, and was there brought under the influence of James Trail, the botanist, and John Struthers, the anatomist, both of whom provided a powerful inspiration which directed him towards a scientific career. After taking medical qualifications at Aberdeen, there followed a brief interlude when he undertook medical work for a gold-mining company in Siam. But it was an interlude of importance, for in his spare time Keith made anatomical studies of the gibbons and monkeys which inhabit the tropical jungles of the Far East and thus laid the foundation of what was to become one of the main themes of his life's work, the comparative anatomy of man and apes. His first paper in this field, which appeared in 1894, dealt with the ligamentous structures of the catarrhine monkeys. In his autobiography (published in 1950), Keith records that on his return from Siam in 1892 he had already decided to embark on an anatomical career; but he had an anxious period of waiting in very straitened circumstances before he was appointed lecturer in anatomy at the London Hospital Medical School. He occupied this post for thirteen years, during which he fully established his reputation as an anatomist by his work on the mechanism of respiration and on the comparative morphology of the heart, and by his important demonstration, in collaboration with Martin Flack, of the sinu-auricular mode of the heart. In 1908 he was appointed to the much coveted position of Conservator of the Museum of the Royal College of Surgeons, a position which he occupied with great distinction until his retirement in 1933.

Arthur Keith's name will always be linked with the Museum of the Royal College of Surgeons, just as, in his time, a reference to the College immediately called to mind the name of Arthur Keith. His distinguished predecessors were essentially academic zoologists and their interests scarcely encroached on the clinical field. But, with his clinical interests and experience, Keith focused attention on the value of the Museum as one of the finest records of the structure and history of the human body, with particular reference to the surgical disabilities and disorders which may affect it. No doubt he was better known in popular circles for his work on human evolution and fossil man; but he was no less well known in the anatomical and clinical field for his numerous and important contributions to the study of applied anatomy. In 1901 there appeared the first edition of his book "Human Embryology and Morphology", the sixth edition of which was published in 1947. The embryology of this book was not based (except to a very slight extent) on original observations; but it had the novel feature of linking together the facts of embryological development with those of comparative anatomy and evolution, and of interpreting the former in terms of the latter. For this reason it proved far more stimulating to students than the more academic and orthodox text-books on human embryology, and it has been very widely used for many years. It exemplifies particularly well the remarkable facility which Keith possessed of clarifying and illuminating an abstruse subject by presenting it in a rather unusual perspective.

At the Royal College of Surgeons, Keith rapidly acquired a high reputation as a lecturer. Although by ordinary standards his delivery was not particularly good—as a speaker he was somewhat halting and hesitant—he had a capacity for making such intimate contact with his audience that each member almost felt that the lecturer was discussing problems with himself personally. From 1910 onwards, Keith devoted more and more time to the study of fossil man, and soon came to be recognized as one of the foremost authorities on this subject. The results of his investigations were published partly in book form (for example, "The Antiquity of Man", 1915) and partly in a series of scientific papers and essays. Many of the conclusions which he formulated in his earlier years, particularly his estimates of a great antiquity for modern types of man based on remains such as the Galley Hill skeleton and the Ipswich skeleton, proved later to be founded on insecure evidence. But it has to be realized that at that time fossil specimens of early man were very few and very fragmentary, and many of the techniques which are available to palæo-anthropologists to-day were as yet undeveloped. One of Keith's outstanding characteristics was a combination of great intellectual honesty with a sincere humility, a combination which is surely a mark of the truly scientific mind, and he was always ready to admit errors of interpretation when the accumulation of evidence demonstrated these. Perhaps no instance of this characteristic is more striking than his immediate acceptance of the fraudulency of the Piltdown specimens when the evidence for this was placed before him last year. As a matter of fact (though he did not himself realize it at the time) Keith actually took the first step which forty years later led to the exposure of the forgery, by demonstrating that the Piltdown skull was that of a large-brained individual similar to *Homo sapiens* and by no means the microcephalic and somewhat simian type of skull which had been exhibited in the first reconstruction from the fragmentary remains.

In 1927, Keith was president of the British Association, and it was the result of his influence on that occasion that Darwin's old home, Downe House, was acquired by the British Association. It was also his influence which led the late Sir Buckston Browne to buy and endow an estate near by for use as an institute of experimental surgery. When Keith retired from his position as Conservator of the Royal College of Surgeons in 1933, he was appointed Master of the Buckston Browne Institute, and occupied that position until he died. He continued his anthropological work there, and in 1939 there appeared (in collaboration with T. D. McCown) what was perhaps one of his best works in this field, an elaborate and careful study of the remains of palæolithic man which had been found at Mt. Carmel in Palestine. He also published in 1948 a book on "A New Theory of Evolution", in which he stressed (and in some ways perhaps rather overstressed) the factor of social segregation in racial diversification, and in 1950 his "Autobiography" appeared.

Sir Arthur Keith's scientific eminence brought him many honours and distinctions; but he remained always a modest and unassuming man. Above all, he will be remembered for his kindly personality. He was (as he himself records in his autobiography) an individualist and did not make friends very easily among his immediate colleagues, but, for all that, he earned an affectionate regard from everyone who had met him, even from the most uncompromising of his scientific opponents

W E Le Gros Clark

Mr J E Sears, C B E

John Edward Sears, formerly superintendent of the Metrology Division of the National Physical Laboratory and, until recently, president of the International Committee of Weights and Measures, died suddenly in Teddington Memorial Hospital on December 21 at the age of seventy-one

The son of the late John Edward Sears, formerly member of parliament for Cheltenham, he was educated at Mill Hill and St John's College, Cambridge, of which he was a Scholar He obtained first-classes in mathematics and mechanical sciences and, in 1907, was awarded the University's John Winbolt Prize for studies in civil engineering He served an apprenticeship with Wigham Richardson, Ltd, Walker-on-Tyne In 1910 he joined the National Physical Laboratory to take charge of the metrology section of the Physics Division and thus became responsible for maintaining the Laboratory standards of measurement in length, mass, area, volume and density, as well as for the associated verification work, including the testing of precision engineering measuring equipment and gauges In 1913, as a consequence of the transfer of test work from Kew Observatory to Teddington, the testing of watches, chronometers, hydrometers, barometers and aneroids was added to the duties of Mr Sears's section During the First World War these duties greatly increased, especially in the development of engineering standards, measuring techniques and apparatus for the verification of all types of limit gauges, of which more than a million were tested at the National Physical Laboratory—a demand upon the Laboratory which arose from the application by the Ministry of Munitions of the principles of interchangeable manufacture to quantity production of weapons and ammunition For his services to the country, Mr Sears was made C B E. in 1920. Another consequence was that his section became established in 1918 as the Metrology Division, with himself as its first superintendent, a post that he held until his retirement in 1946 During 1921–32 he was concurrently deputy warden of the standards at the Board of Trade

Mr. Sears's pioneer work in metrology is without parallel in Britain He combined outstanding powers of leadership and organization, a broad scientific knowledge, a flair for design and a clear perception of the basic metrological principles These qualities, with his numerous contributions to the literature, his initiation and supervision of several researches of fundamental importance and the many examples of prototype measuring equipment developed under his personal direction, brought the Laboratory international renown in the subject which was of such absorbing interest to him Among the work with which his name is especially associated may be mentioned a determination of the yard and the metre in wave-lengths of light, and of the refractive index and dispersion of air

Mr Sears was a member of the Institution of Mechanical Engineers and in 1948 he was awarded part of the Institution's Clayton Prize for his services to engineering science and manufacture by research and development in metrology and gauging His presence on committees of the British Standards Institution was always in demand, particularly as chairman, and he continued his work for the Institution until the end He was a member of the Hodgson Committee of the Board of Trade which reported in 1951 its recommendations for the revision of weights and measures legislation Only in October last he retired from the International Committee of Weights and Measures, to which he had been elected in 1930 His election as president in 1946, a position of considerable influence and renown in the international metric organization, was a great honour not only to himself but also to the United Kingdom

In earlier days Mr Sears was a skilled exponent of the English style of skating, and he took a leading part in many of the social activities of the National Physical Laboratory He had a keen interest in gardening and was a Fellow of the Royal Horticultural Society He married in 1919 Kathleen Lucy, daughter of the late Edward Wadsworth, who survives him together with a son and two daughters

H Barrell

NEWS and VIEWS

Rhodesia University College Appeal

The inaugural board of the Rhodesia University College has prepared a handsome illustrated brochure for circulation as a part of its campaign for funds and with the object of publicizing the College generally (see also p 181) Messages are recorded therein from Lord Llewellyn, the Governor-General of the Federation of Rhodesia and Nyasaland, from Sir Godfrey Huggins, the Prime Minister of the Federation, and from other distinguished men An outline of the history of the founding of the Rhodesia University College is given, and the 'special relationship' with the University of London which will exist in the early years is discussed An artist's drawing of the University as it is expected to appear when the proposed buildings are completed shows an imaginative treatment of the site, which is on the outskirts of Salisbury, Southern Rhodesia The £450,000 for which the present appeal is launched is the balance still needed of the £2,000,000 required during the early years of the College's existence Subscriptions and any requests for further information should be addressed to the Secretary, Rhodesia University College, 115 Baker Avenue, Salisbury, Southern Rhodesia.

Dr Walter Adams, C M G, O B E

Dr. Walter Adams has been appointed the successor of Dr W Rollo as principal of Rhodesia University College from November 1955, when Dr Rollo's interim appointment comes to its close Dr Adams is at present secretary of the Inter-University Council for Higher Education in the Colonies, an appointment which he has held since the inception of the Council in 1946 He was born in 1906, and graduated at University College, London, with first-class honours in history, in 1926. Between 1926 and 1933 he held a number of research and teaching appointments in history in the University of London In 1933 he became general secretary to the Society for the Protection of Science and Learning, a body which did invaluable work in helping to place academic refugees from Germany and other places in suitable positions In 1938 he became secretary of the London School of Economics and Political Science, University of London—a position which he held until he took up his present one, though during 1941–45 he was seconded for service with the Foreign Office, spending some time in Washington as deputy head of the British Political Warfare Mission to the United States He was made O B E in 1945 and C M G. in 1952 In his present post, Dr Adams has necessarily travelled widely and has obtained much experience of the problems of university education in Colonial territories Early in 1954 he was awarded the honorary degree of LL D by the Royal University of Malta He will take to the Federated Territories of Central Africa, which he already knows, a knowledge of the educational problems to be faced in multi-racial territories which few can rival The great experiment in higher education upon which Central Africa is about to embark needs men of integrity, experience and forcefulness for its successful outcome, and in Dr Adams a principal has been found who, like Dr Rollo before him, enjoys to the full these and many other distinguished attributes.

Sir Bernard Keen, F R.S.

Sir Bernard Keen, who has been director of the East African Agriculture and Forestry Research Organization since 1947 (see *Nature*, **160**, 184, 1947), is retiring in August He was the first physicist to tackle soil problems in Great Britain This pioneering work at Rothamsted Experimental Station opened up a hitherto neglected line in pure physics—the study of water distribution and movement in porous materials—as well as providing practical applications to agriculture, notably in soil cultivation, evaporation and transpiration Hydrological problems of much importance in connexion with water resources were also clarified by the work of the Soil Physics Department Apart from two years secondment (1929–31) to reorganize the Imperial Institute of Agricultural Research in India, and extensive visits to the United States and South Africa, he remained at Rothamsted as head of the Soil Physics Department and assistant director until 1943 During 1943–45 he was scientific adviser to the Middle East Supply Centre In 1946 he was appointed adviser on soil conservation to the Government of Palestine, and chairman of a U K Government Mission to West Africa on vegetable oil production In 1947 he made an extensive tour of East Africa to advise on regional research The outcome was the adoption of a Colonial Development and Welfare Scheme to create the East African Agriculture and Forestry Research Organization, of which he became the first director A nucleus of staff was available at the East African Agricultural Research Institute at Amani in Tanganyika, which was absorbed into the new Organization The staff was increased by recruitment as the laboratories and experimental farm at the new headquarters near Nairobi approached completion Much attention was given to the important problems of co-ordination between the long-range research of a regional organization and the territorial investigations conducted by the Agriculture, Forestry and Veterinary Departments of Kenya, Tanganyika and Uganda Close liaison was also established with other bodies, such as the Cotton Research Station of the Empire Cotton Growing Corporation, the East African Tea Research Institute, the Overseas Food Corporation, and the Tanganyika Sisal Association Research Station

Chemistry at Glasgow

Prof D H R Barton, F R S

D H R Barton, who has been appointed regius professor of chemistry in the University of Glasgow in succession to Prof J W Cook (see *Nature*, **173**, 61, 1954), graduated at the Imperial College of Science and Technology, University of London, in 1940 He obtained the Ph D degree for work under Sir Ian Heilbron in 1942 and engaged in government work during 1942–44 After a short time in industry, he returned to the Imperial College to work in the Department of Inorganic and Physical Chemistry under Prof H V. A Briscoe, at first as a junior member of staff and later as an I C I Research Fellow. After a year as visiting lecturer in the chemistry of natural products at Harvard University, where he understudied Prof R B Woodward, Dr Barton returned to Britain to take up an appointment as reader in organic chemistry at Birkbeck College, University of London, he was elected professor of organic chemistry in the University of London in 1953 Prof Barton was Harrison Memorial prizeman of the Chemical Society in 1948 and the first Corday-Morgan medallist of that Society in 1951 In 1952 he was a Tilden lecturer of the Chemical Society and was elected to the fellowship of the Royal Society in 1954 His scientific work is summarized in more than a hundred scientific communications in organic and physical-organic chemistry He is responsible, in part, for the development of molecular rotation correlations and conformational analysis, concepts which are contributing greatly to the current rapid growth of alicyclic natural-product chemistry

The International Union of Biochemistry

The International Union of Biochemistry, which was founded on March 1, 1953, was formally constituted at its first general assembly, held in London during January 5–6 Of the fifteen countries which adhere to the Union to date, the following twelve were represented at the Assembly Austria, Belgium, Denmark, France, Germany, Italy, Japan, the Netherlands, Sweden, Great Britain, U S A and U S S R The Assembly elected the Council of the Union, and the Council appointed from among its members the following office-bearers *President*, Prof M Florkin (Belgium), *Treasurer*, Prof E H Stotz (U S A), *Secretary-General*, Prof. R. H. S. Thompson (Great Britain) The following delegates from the various countries at present adhering to the Union make up the remaining members of the Council Prof S Akabori (Japan), Prof J Courtois (France), Academician V A Engelhardt (U S S R), Prof A H Ennor (Australia), Prof K Felix (Germany), Prof E Hammarsten (Sweden), Prof. O Hoffmann-Ostenhof (Austria), Prof K Linderstrøm-Lang (Denmark), Prof. K Lohmann (Germany), Prof R Nicolaysen (Norway), Prof S. Ochoa (U S A), Academician A. I Oparine (U S S R), Sir Rudolph Peters (Great Britain), Prof J Roche (France), Prof A Rossi-Fanelli (Italy), Prof A. Virtanen (Finland) and Prof. H. G. K. Westenbrink (Netherlands). Sir Charles Harington, the former chairman of the International Committee for Biochemistry which was set up at the first International Congress of Biochemistry at Cambridge in 1949, was elected an honorary member of the Council. Following on the unanimous decision of the Assembly, a formal application has now been made on behalf of the Union for adherence to the International Council of Scientific Unions

British Universities Film Council

THE report of the British Universities Film Council for 1953–54 is the sixth since its foundation, which was largely due to the initiative of members of the University Educational Film Council of Cambridge The Council has welcomed the Universities of Aberdeen and Manchester to ordinary membership, making this total now thirty-one, the Scientific Film Association has been admitted to associate membership The report refers to a few of the many activities of the British Universities Film Council, one of which is the issue to all member institutions of a card index giving full particulars of 16-mm films likely to be of use at some stage or other in teaching at university-level or research This list is useful for preliminary reference purposes and gives, under subject headings, the titles of index films Realizing that such a carefully prepared and comprehensive list may be of value to many people and organizations besides their members, the British Universities Film Council has made copies available to all who are interested They may be obtained from the Catalogue Secretary, Royal Technical College, Glasgow

Health Education throughout the World

THE Fifth World Health Assembly, held in May 1952, made provision for the convening of an expert committee on the health education of the public This committee held its first meeting in Paris during December 1953, and its report has now been published (Technical Report Series No 89 Expert Committee on Health Education of the Public First Report Pp 41 (Geneva World Health Organization, London H M Stationery Office, 1954) 1 Swiss franc, 1*s* 9*d* net, 0 25 dollar) The committee tried to outline the way people learn, and the role of the educator in health programmes, to state the broad principles of programme planning, evaluation and organization, and to describe the development and use of methods and media, and the desirable training of personnel Particular attention has been given to the importance of the learner, the 'consumer' of health education, too often in the past health education activities have relied on the wide use of educational media with insufficient consideration of the people for whom they were intended. The report also contains examples of how actual health education campaigns have been carried out in rural, semi-rural and urban areas It would be interesting to know whether health educators throughout the world gain more from these three short case-studies or from the detailed statement of general principles which forms the bulk of the report

Interaction in Effects of Plant Growth Substances

VARIOUS interactions in the physiological effects of growth substances on plant development have been investigated and discussed by G E Blackman and R C Robertson-Cuninghame (*J Exp Bot*, **5**, No 14, 184, 1954) The interrelated effects of 3-indolylacetic acid and sodium 2 4-dichlorophenoxyacetate on the growth and development of *Lemna minor* and *Helianthus annuus* have been investigated by means of multifactorial experiments, involving three to five levels of each compound A clonal population of *L minor* was maintained under constant conditions of light (550 foot-candles) and temperature (25° C) and the growth regulators were added to a phosphate-buffered culture solution (*p*H 5 1) which was changed every two days In the *H annuus* experiments the compounds, in aqueous solution, were placed by means of a micro-pipette on the leaves of young plants grown in a greenhouse or in the open Indolylacetic acid, at concentrations up to 25 p p m, increases the relative growth-rate of *L minor* on either a dry-weight or frond-area basis Sodium dichlorophenoxyacetate at 0 025 p p m. has little effect on growth, but at and above concentrations of 0 2 p p m growth is depressed The ratio of frond area to total dry weight is increased by indolylacetic acid, but is depressed by the phenoxyacetate In the presence of indolylacetic acid, more particularly at the higher levels, the relative inhibition of growth caused by sodium dichlorophenoxyacetate is reduced Various results with *Helianthus annuus* are also described The authors conclude that the results which they have obtained in these experiments cannot be explained on the concept of wholly additive effects There is evidence that the compounds can mutually interfere in their actions, and it would seem that more than one mechanism is involved. Many of the results can be satisfactorily interpreted on the basis that the two compounds act on a common system and that they compete with one another, but the results are not compatible with the postulate that the dichlorophenoxyacetic acid directly inactivates indolylacetic acid.

Some Tungsten and Molybdenum Products

ELECTRO-ALLOYS, LTD, 47–49 Brunel Road, Acton, London, W 3, have issued an attractive and informative illustrated catalogue of their tungsten and molybdenum products The content is printed in three languages—English, French and German—and covers the use of tungsten as a contact material, tungsten and molybdenum as lead-in-wires for glass to metal seals, tungsten welding electrodes for inert-gas arc welding, molybdenum tubes and rods, tungsten anodes for X-ray tubes, tungsten and molybdenum heaters for vacuum metallizing plant and for other special components required for the electronic and associated industries. The technical and physical characteristics of the two metals are clearly stated, whereas both metals have high melting points, low coefficients of thermal expansion and relatively good electrical conductivities at room temperature, their mechanical properties differ in that tungsten cannot be turned, threaded or drilled

The British Gelatine and Glue Research Association

THE annual general meeting of the British Gelatine and Glue Research Association was held on December 8 at the Connaught Rooms, London, W C 2 Mr S G Hudson (Messrs Richard Hodgson and Sons, Ltd.), chairman of council, was in the chair In presenting the annual report, Mr Hudson commented on the extent of the Association's scientific publications, and on the facilities now available to assist member firms Mr A G Ward, director of research, described how the original decision of the industry, to concentrate the work of the Association on fundamental research, was gradually giving rise to results of practical significance. Mr. G. W. Odey (Messrs. Barrow, Hepburn and Gale, Ltd.) was re-elected president. Mr. Odey stressed the importance of applying the most intensive scientific examination to natural products to make the greatest use of the structure with which they have been endowed. There were no changes in the Council or Committees of the Association.

Agricultural Scholarships

The Ministry of Agriculture and Fisheries is offering a limited number of senior and junior scholarships to the sons and daughters of agricultural workmen, smallholders and other rural workers, and to persons who have been paid workers on the land for at least three years. The scholarships are for courses in an agricultural or allied subject, including veterinary science, at university departments of agriculture, agricultural colleges and farm institutes. Candidates must have attained the age of seventeen by September 30. Further information can be obtained from the Secretary, Ministry of Agriculture and Fisheries (Room 313), 1 Cambridge Terrace, Regent's Park, London, N.W.1, or from education offices of county councils.

The Night Sky in February

Full moon occurs on Feb. 7d. 01h. 43m., U.T., and new moon on Feb. 22d. 15h. 54m. The following conjunctions with the moon take place: Feb. 5d. 07h., Jupiter 2° N.; Feb. 14d. 14h., Saturn 6° N.; Feb. 18d. 21h., Venus 1° N.; Feb. 21d. 08h., Mercury 0·5° S.; Feb. 26d. 20h., Mars 4° S. Mercury sets at 18h. 25m., on Feb. 1, which is about 1½ hr. after sunset, and will be visible in the western sky; but the planet is rapidly drawing closer to the sun, with which it is in inferior conjunction on Feb. 12. Towards the end of the month it rises about an hour before the sun, but its declination is then 15° S. and it will not be an easy object to see. Venus rises at 4h. 45m., 5h., and 5h. 10m. at the beginning, middle and end of the month, respectively, and is visible in the eastern sky; but owing to its fairly large southern declination it does not attain a great altitude. Its stellar magnitude varies from −4 to −3·8 and the visible portion of its illuminated disk from 0·547 to 0·650. The distance of Venus from the earth varies from 67 to 86 millions of miles during February. Mars sets about 22h. 25m. during the month and is visible in Pisces from which it moves into Aries, its stellar magnitude varying from 1·2 to 1·4, largely owing to its distance from the earth increasing by nearly 20 million miles during February. Jupiter sets in the morning hours, being visible during the night; its times of setting are 7h., 6h. and 5h., on Feb. 1, 14 and 28, respectively, and it has a westward movement in Gemini, its stellar magnitude varying from −2·1 to −2·0, the decrease in brightness being due to its distance from the earth increasing by 23 million miles during the month. Saturn rises at 1h. 55m., 1h. 05m. and 0h. 10m. at the beginning, middle and end of the month, respectively. It moves slowly towards γ Librae but is stationary at the end of the month, after which it has a westward movement. Its stellar magnitude is 0·7 at the beginning and 0·65 at the end of the month, owing to its distance from the earth decreasing by 42 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Feb. 1d. 0h. 19·0m., ζ Ari (*D*); Feb. 2d. 19h. 14·8m., 103 Tau (*D*); Feb. 3d. 18h. 11·9m., 3 Gem *m* (*D*); Feb. 4d. 1h. 05·3m., μ Gem (*D*); Feb. 4d. 1h. 46·6m., μ Gem. (*R*); Feb. 4d. 23h. 45·7m., 56 Gem (*D*); Feb. 10d. 6h. 01·4m., 13 B. Vir (*R*); Feb. 28d. 19h. 02·6m., 133 *B*. Tau (*D*); Feb. 28d. 22h. 08·3m., 32 Tau (*D*), where *R* and *D* refer to reappearance and disappearance, respectively.

Announcements

The second International Seaweed Symposium will be held in the Norwegian Technical University, Trondheim, during July 13–17. Further information can be obtained from Prof. T. Braarud, Blindern, Oslo.

The annual conference of the Museums Association will be held at Birmingham during July 4–9. Further information can be obtained from the Secretary, Museums Association, 33 Fitzroy Street, Fitzroy Square, London, W.1.

The eighth Laboratory Animals Bureau Congress will be held in Oxford during March 28–29. The third symposium on "Breeding of Laboratory Animals", organized by the Bureau, will be held at the Royal Society of Medicine on May 9. Further information can be obtained from the Laboratory Animals Bureau, M.R.C. Laboratories, Holly Hill, Hampstead, London, N.W.3.

The annual Spring Conferences in the Department of Industrial Metallurgy, University of Birmingham, will be held during March 14–15. The subject for March 14 will be "Graphitization in Cast Irons", and for March 15 "The Structure and Properties of Electrodeposited Metals and Alloys". Further information can be obtained from the Secretary, Department of Industrial Metallurgy, The University, Birmingham 15.

The Massachusetts Institute of Technology is offering assistantships and fellowships for students taking the two-year course leading to the degree of master of science in industrial management. Assistantships are valued at 1,640 dollars and fellowships at 2,300 (3,000 for married students) dollars a year. Further information can be obtained from the Chairman of the Graduate Committee, School of Industrial Management, Massachusetts Institute of Technology, Cambridge 39, Mass., U.S.A.

The Trustees of the Lady Tata Memorial Fund invite applications for grants, scholarships or fellowships for research on diseases of the blood, with special reference to leukæmia, during the academic year beginning on October 1, 1955. Further particulars and forms of application may be obtained by writing to the Secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, 38 Old Queen Street, London, S.W.1; applications must be submitted before March 31.

The Worshipful Company of Glass-Sellers of London is offering up to four scholarships in glass technology tenable at the University of Sheffield which, in suitable circumstances, qualify for supplementation by the Ministry of Education up to the full value of State scholarships. The scholarship examination consists of papers in chemistry, physics and pure mathematics (two as primary subjects and one as a secondary subject) together with an English language paper. Applications for entry should be made to the Registrar, University of Sheffield, Sheffield 10, before February 26.

SURVEY OF FIELD THEORY

AUTUMN MEETING OF THE PHYSICAL SOCIETY

MOST meetings of the Physical Society are intended either for the presentation of original papers or for hearing a special lecture by a distinguished scientist, usually the recipient of one of the Society's awards. The meeting held at the University of Birmingham on December 14–15 was of a rather different type. It may fairly be described as a conducted tour of one of the most interesting regions of the frontier of our present knowledge. The 'guides' were a team of specialists on field theory, under the leadership of Prof. R. E. Peierls, who gave the introductory lecture on the first day, when the president of the Physical Society, Prof. H. S. W. Massey, took the chair. The meeting was intended for experimentalists with a general knowledge of quantum mechanics and for theoreticians who do not specialize in field theory.

The lectures themselves were highly condensed summaries, so that it is not possible to summarize them further, but a general indication of their contents may be of interest to readers of *Nature*. Prof. Peierls, in the opening lecture, introduced the fundamental ideas, starting with a consideration of the normal modes of vibration of a solid. He emphasized the method of specifying quantum numbers for the different frequencies and derived from this the picture of 'sound quanta'. These sound quanta, known as 'phonons' in the physics of the solid state, carry the vibrational energy like separate particles. Prof. Peierls then discussed the Fourier analysis of the electromagnetic radiation field and its quantization. Again the quantum numbers for different frequencies specify the field, and the photons replace the phonons. He extended the description to static fields considered in terms of an exchange of longitudinal photons between the charges. The skeleton in the cupboard—the infinite energies—was brought out, rattled and then put back again. Field theorists appear to have a normal vibration between two states: in one they believe they have solved the problem of the infinities, and in the other they know that they have not. Just at present, the first state seems to have the higher occupation number. Prof. Peierls described the virtual processes in which the field theorist becomes a dishonest accountant who embezzles energy but is never found out because he makes restitution within a time fixed by the uncertainty relation.

Dr. A. Salam (St. John's College, Cambridge) gave a more detailed analysis of field quantization and extended the analysis to a field of "photons of non-zero rest mass" defined by the Klein–Gordon equation. He showed that the 'particles' had some at least of the properties of π-mesons. He expounded and re-interpreted the Dirac theory of the electron. Dr. P. T. Matthews discussed interaction between fields and analysed a number of virtual processes. These virtual processes play a very important part in, and are a distinctive feature of, modern field theory. The scattering of a photon of frequency ν by an atom which has two states of energy E_1 and E_0 is regarded as including an intermediate process in which the photon is absorbed and the atom goes from E_0 to E_1, but since $h\nu$ is not even approximately equal to $E_1 - E_0$, energy is not conserved in this process. However, there is a second process in which the photon is emitted in a new direction and the atom returns to its original state. The second stage also 'breaks' the conservation law, but the two stages taken together do not, and there is no observable breach of the law. The 'ordinary physicist' who is just reconciling himself to this situation is then told that he must also accept a situation in which the photon is emitted from the atom in changing from state E_0 to state E_1, that is, 'before' the absorption of the incident photon. He is in the position of a bank manager who has agreed, in principle, that he will grant overdrafts and is then approached by someone who wishes to 'open an account' with an overdraft! As Dr. Matthews showed, there is no logical difference, but the psychological impact of the unfamiliar idea is sharper. He showed that successive virtual processes may produce unexpected observable effects. This gave a theory of the Lamb–Retherford shift and of the 'anomalous' magnetic moment of the electron. He explained the difficulty of meson theory which arises because the fundamental constant $g^2/\hbar c$ is probably of order 10, whereas the corresponding constant in electron theory, $e^2/\hbar c$, is 1/137.

During the discussion on these papers, experimentalists asked what the field theorists had to say about experiments in which particles seem to be very individual, for example, the observation of the track of a meson in an emulsion. Prof. Peierls stated the conditions in which the particle concept remains useful, but emphasized that the field concepts are an essential feature of any relativistic theory of interactions. There was a certain amount of friendly banter between the lecturers and some of the experimentalists in the audience concerning the question whether theory had preceded or followed certain experimental results. If an onlooker may comment on this private contest, I feel that life would be dreadfully dull for the experimentalist if the theoretician could predict in advance the results of his experiments. The theory which is most useful to the experimentalist is the one which most clearly defines a limited area in which crucial experiments may be expected to produce important results.

The three lectures on the second day dealt chiefly with field interactions. Dr. Matthews considered the information about spin, parity, etc., which is derived from studies of the disintegration of π-mesons and their interactions with nucleons. The independence of charge shown by nucleon–nucleon forces was discussed and the concept of isotopic spin was introduced. Dr. G. Feldman described meson production and scattering experiments, giving particular attention to the high-energy resonance effects obtained with protons produced in the large accelerators. Prof. Peierls gave the concluding lecture, in which he summed up the earlier discussions and described some of the difficult unsolved problems connected with the heavier mesons and the hyperons. He referred—perhaps a little wistfully—to the period in the 'thirties when it was believed that an understanding of the dimensionless constant $e^2/\hbar c$ was just around the corner, and that with this understanding all problems of fundamental particles and nuclear forces would be solved . whereas to-day people don't know where to stop

The Physical Society and the organizers made the conference open without fee to all who were interested. Probably about half those present were Fellows or student members of the Society and rather more than half were visitors to Birmingham The total attendance was 135 Among this large number, there must have been a few whose background knowledge was insufficient, but the interest and enthusiasm of the meeting was maintained throughout, the audience at the last lecture was not noticeably less than that at the first Inquiries revealed a general feeling that an additional day or half-day to give time to assimilate the material would have been useful, but this statement was repeatedly accompanied by expressions of admiration for the excellence of the lectures It was possible to treat so much material in a short time only because very great care had been taken to devise a treatment which avoided all purely mathematical difficulties while revealing the essential unsolved problems of physical understanding

In concluding this report, it is reasonable to ask whether this meeting should form an example for some future meetings of the Physical Society If specialists in some other fields are prepared to give as much thought to the problems involved in explaining their work to other physicists, then they may also succeed, for example, a similar treatment of problems of supersonic flow might be very interesting Other scientific societies may also find occasional meetings of this type acceptable to their members

R W DITCHBURN

THE GEOGRAPHICAL ASSOCIATION

THE annual conference of the Geographical Association held at the London School of Economics during January 4–7 concluded a further eventful year in the life of the Association, although the year's activities were sadly clouded by the death of Dr O. J R Howarth, the immediate past-president, and also of Sir John Myres, a trustee, past-president and very staunch friend of the Association

A very successful spring conference was held amid delightful surroundings at Exeter, and the summer school, under the leadership of Mr R C Honeybone and Dr K A Sinnhuber, embarked on a new venture by meeting at Sistrans, near Innsbruck A second party of members also attended in August the International Conference of Teachers of Geography held at Hilversum As an outcome of this meeting the Geographical Association's office was adopted as the headquarters for the International Union of Associations of Teachers of Geography As the central co-ordinating body, the Association has now assumed responsibility for the development and exchange of ideas among teachers of geography throughout the world The Association has also sponsored courses for teachers in co-operation with the Norfolk Education Committee at Wymondham College, with the Derbyshire Education Committee at Buxton, with the Lancashire Education Committee at Manchester, and with Institutes of Education at London, Nottingham, Leeds and Reading

A lively branch activity continues, five new branches being formed during the year, thus bringing the total to forty-six, and the membership has risen accordingly and now approaches the four thousand mark The Association has watched with care the status of geography in the schools, and one important matter upon which questions were asked in the House of Commons was concerned with the changing regulations of the Scottish Universities Entrance Board Action was taken jointly with the Royal Geographical Society and the Institute of British Geographers in this instance At present considerable interest is focused upon the position of geography in secondary modern schools, comprehensive schools and technical schools

The three hundred and fifty teachers and lecturers who attended the annual conference were thus able to note with satisfaction a year of continuing vigorous activity under the presidency of Prof S W Wooldridge In a stimulating and provocative presidential address on the "Status of Geography and the Role of Field-work", Prof Wooldridge directed attention to the need for a closer liaison between university and school practitioners of the subject, and to the problem of achieving balance between the presentation of matter and methods of teaching in the training colleges The principles of field-work were enumerated and the need for local studies was emphasized, while the work of the Council for the Promotion of Field Studies was described together with the geographical facilities available at the four centres at Juniper Hall, Flatford Mill, Malham Tarn and Dale Fort.

The wide range of interests of the geographer was well illustrated by the supporting lectures Mr T. H Elkins spoke on Liège and the problems of southern Belgium, Mr D J Sinclair gave the results of a study in historical geography of some Surrey farms in the eighteenth and nineteenth centuries, Dr F. G Hannell lectured on the activities of the British Schools Exploring Society, and Mr R C Honeybone presented an account of the summer school's alpine field-studies

Educational aspects centred on a lecture by Mr Charles Armour (of the British Broadcasting Corporation) on school broadcasting and the teaching of geography, the talk being enlivened by recorded extracts from programmes and on three symposia arranged by section committees One dealt with problems of geography teaching and their relation to preparation for the university, a second discussed the General Certificate of Education of the Associated Examining Board, and a third—supported by a demonstration class—considered techniques of diagram and map-making in class A selection of recent geographical films was shown during the meeting, and Prof. P W Bryan once again contributed a 'Kodachrome' colour film, dealing on this occasion with the north-east Yorkshire moors, wolds and coast The customary publishers' exhibition of books, maps and appliances for the study and teaching of geography, supported by nearly forty publishers, was also arranged. The Association's Standing Committee for Visual Aids, in collaboration with the National Committee for Visual Aids in Education and the Educational Foundation for Visual Aids, also mounted an exhibition of visual aids and apparatus under the theme of "Ways of using Visual Aids in the Classroom".

Social activities at the conference included a summer schools reunion supper, a section luncheon, an Association tea, and the largest annual dinner yet held, at which Prof P W Bryan, Mr F Spencer Chapman and Mr Charles Armour were the guests On January 6 the Association met jointly with the Royal Geographical Society to hear Mr F. Spencer Chapman describe his "African Journey", and this terminated the more formal part of the conference On the last day, however, an interesting series of excursions had been arranged to places of geographical interest Conducted visits were paid to St Albans, Rothamsted Experimental Station, the Port of London, the Ordnance Survey and Messrs George Philips Map and Globe Works

The new year is entered upon with considerable changes among the officers of the Association. Mr T C. Warrington is now retiring after many years of service as honorary auditor and honorary librarian, and these two offices will in future be filled by Mr W. R A Ellis and Mr L J Jay Mr L S Suggate becomes president for 1955, while Mr R C Honeybone takes over from Prof W G V Balchin the post of honorary conference organizer Prof L Dudley Stamp, Prof E G Bowen and Prof W G V Balchin have been elected trustees of the Association

W G V Balchin

SCIENCE MASTERS' ASSOCIATION

ANNUAL MEETING AT NEWCASTLE UPON TYNE

MORE than four hundred science masters met in King's College, Newcastle upon Tyne, during the week between Christmas and New Year for the annual meeting of the Science Masters' Association The world-wide reach of the Association is shown by the fact that teachers were present from Ceylon, Nigeria, Uganda and Natal, also present were Mr Withers, secretary of the Education Section of the Federation of British Industries, Dr Dewar, representing Imperial Chemical Industries, Ltd, and Mr Obourn, an American observer from the Paris headquarters of Unesco

The first evening was the occasion of the presidential address by Dr C I C Bosanquet, rector of King's College This was delivered to a crowded audience in the large lecture theatre of the new Chemistry Building, remarkable for the excellence of its acoustics and of its air-conditioning system Dr Bosanquet's address was entitled "In Praise of Natural Philosophy" and was a plea for the broadening of the school curriculum for both the science and the arts specialists, the scientist, he said, is at present given a training only in a series of unrelated subjects, and the arts specialist is deprived of any further acquaintance with the great processes of Nature Dr Bosanquet quoted figures which showed that while the number of pupils taking science in schools is steadily rising, the number taking arts is almost stationary, and there is still a considerable proportion of boys in the public schools doing little or no science at all. As an example of the synthesis involved in the term 'natural philosophy', Dr Bosanquet dealt at some length with the life of Thomas Young, who was equally good at so great a variety of subjects Dr Bosanquet wants it to be possible for a student on reaching the university to change over from an arts course to a science one and vice versa He concluded by emphasizing the necessity for inculcating a sense of responsibility in the young scientist, he thought that wars are less likely to come from irresponsible rulers than from the apathy of those they rule, the young scientist should understand clearly that, in any future war, his chance of remaining unhurt is small

Among its many activities, the Association administers a trust fund for the presentation of a lecture on science and citizenship, usually given every second year This year the lecture was by Dr Eric James, High Master of Manchester Grammar School, and it will live long in the memories of those who heard it as a great occasion in the history of the Association, an excellent speaker giving out constructive thought at white heat in a splendid theatre to another crowded audience made it a remarkable experience Dr James took the view that the scientist cannot be a neutral technical expert, and must take full responsibility for the consequences of his work Even if that work be apparently without any practical application whatever, he still owes the opportunity to do that work to the social structure in which he lives, and he can therefore not afford to be indifferent to circumstances affecting that structure

Dr James expressed concern at the consequences of television, the "most politically significant invention since printing", since it creates masses of uncritical observers, and might prevent the heretic and the oddity, on whom progress depend, from having any public voice at all He thought also that as more and more of the best brains become involved in scientific pursuits, there is a grave risk that the level of ability in political administration may fall, and it is therefore essential that the scientist should have an education making him capable of taking over the work of government.

The more strictly scientific activities during the meeting included lectures by members of the science and applied science faculties of King's College Notable among these was one entitled "Demonstrations in Optics", by Prof W E Curtis, who is an outstanding example of that not too common combination, high ability as a scientist and great skill as a showman, all his very large number of experiments were most beautifully presented

On the same morning, Prof W F K Wynne-Jones gave a lecture on the presentation of physical ideas in chemistry, and Prof A D Hobson followed up a lecture on the marine fauna of the British Isles with an afternoon visit for members to the Marine Laboratory at Cullercoats

The second full day began with a lecture by Dr R McWeeny on the impact of quantum theory on the teaching of physics and chemistry, one by Prof T S Westoll on "Living Fossils", and one by Prof G S Rushbrooke on some characteristic features of twentieth-century physics Prof Westoll's lecture, on a semi-palæontological subject, marks a somewhat unusual departure for the Association, and indicates a steady broadening of its subject-matter •King's College has plans for a large new department of geology, in view of the importance of that study to the north-eastern area of Britain

The two main afternoons were occupied by visits to many different industrial organizations, such visits being indeed a strong point of the meeting, since the North East includes so many types of heavy and light industry. The sites visited included the Wilton and Billingham works of Imperial Chemical Industries, Ltd., the Pyrex glass works at Sunderland, two coal mines, factories making springs and pumps, works for gas, soap and mining machinery, the Ediswan lamp and valve factory, Parsons and Marine Engineering Turbine Research and Development Association, Reyrolles switchgear works, and the premises of Associated Lead Manufacturers, and of the Grubb Parsons Optical Co., Ltd. A visit was also made to the Radiochemical Laboratories at Durham, where accurate analyses of small quantities of rare gases are performed. Samples of gas from the upper atmosphere, taken in the United States by means of rockets, are sent to Durham for analysis.

The meeting also included discussions on M.K.S. units, on science teaching in secondary modern schools, and on science and religion.

The final morning again began with lectures, by Dr. S. L. Ranson on the metabolic activities of cellular particles, Dr. J. H. Wilkinson on small-scale organic preparations, and Mr. P. C. G. Isaac on public health engineering.

During the meeting, all the science and engineering laboratories of King's College were open, and members, manufacturers and publishers again gave their usual exhibitions; the manufacturers and publishers expressed great satisfaction at their excellent housing in the new Chemistry Building.

Special exhibitions were also arranged by the Northern Lighting Bureau of the Electric Lamp Manufacturers' Association and by the British Iron and Steel Federation. For the former, the area representative, Mr. R. J. Fothergill, had prepared a fascinating experimental display, including, in a corridor, an illuminated sign, the light from which detected whether one's shirt had been washed in particular detergents. For the Iron and Steel Federation, Capt. J. F. W. Mudford, area training organizer, had a comprehensive collection of all the Federation's educational literature, together with specimens and static models of its productions.

The social side of the meeting was catered for by an evening concert in King's Hall, preceded by a reception at which members and their ladies were welcomed by the Lord Mayor and Lady Mayoress of Newcastle upon Tyne, the Rector of King's College, and the Chairman of the Association and Mrs. Dyball. The playing in of the Lord Mayor by the Northumbrian pipes of Mr. Jack Armstrong was a touch characteristic of the locality, and the concert, which included piano solos by Miss Margaret Evans, Northumbrian songs by Mr. William Robinson, and pipe music by Mr. Armstrong, was much appreciated.

The Association is deeply indebted to all those who helped with the preparation of the meeting, and especially to the registrar, Mr. G. R. Hanson, to Prof. W. F. Cassie, who arranged the tours of the engineering laboratories; and to Dr. Chalmers Burns, director of music, who obtained the artistes for the concert.

It may be permissible to quote the final comment of a witty member from a famous Scottish public school, who said that he was going home "a wider and a humbler man, wider in that he had been fed so well, and humbler in that he had learnt so much".

W. H. DOWLAND

THE BRITISH FLORA DURING 1954

THE flora of the British Isles has been the subject of such thorough investigation, as compared with most other countries, that advances in knowledge can now be expected mainly from the application of new techniques and from the closer study of small groups. These were the approaches adopted by most of the exhibitors at the annual exhibition meeting of the Botanical Society of the British Isles, arranged in the lecture room of the British Museum (Natural History) on November 28. It was evident that cytology and careful analysis of variation are still yielding some of the most interesting results, and that the study of hybrids is proving of far greater importance than was supposed a few years ago.

One entirely new development was illustrated by H. J. M. Bowen (Radiobiological Research Unit, Atomic Energy Research Establishment, Harwell). By means of activation analysis—the ashes being irradiated with neutrons in the Harwell pile, and the radioactive strontium then separated from all the other elements by conventional methods—he has determined the amount of strontium present in material from about forty species of plants. He finds that plants growing on ordinary soils contain 1–50 parts per million of strontium, but in the limited areas in Britain where the soils contain large concentrations of this element (as the sulphate, celestite; or as the carbonate, strontianite), plants are found to contain up to 2 per cent or more of strontium by dry weight. All the species examined were found to be accumulators. The Avon Gorge is one of the areas where considerable concentrations occur in the rocks, and the concentrations in some of the rare species found there (for example, *Arabis stricta* 1·06 per cent, *Anisantha madritensis* 1·16 per cent) are also high. Further investigation may show that the distribution of certain plants may be related to concentrations of strontium.

A number of very interesting hybrid grasses were exhibited. Dr. A. Melderis (British Museum (Natural History)) showed *Festuca rubra* × *Vulpia membranacea*, which was collected by several members on the Society's field meeting at Southport, and later by Miss M. McCallum Webster on dunes at Sandwich. In both places it evidently occurred in some quantity. A similar hybrid was exhibited by C. E. Hubbard (Royal Botanic Gardens, Kew) from Vazon, Guernsey. He also showed *Agrostis stolonifera* × *A. semiverticillata* from Vazon, *Festuca arundinacea* × *Lolium perenne*, and a variegated form of *Poa annua* from a shrubbery at Kew. With N. Y. Sandwith (Royal Botanic Gardens, Kew) he exhibited *Agropyron repens* × *Hordeum secalinum* (× *Agrohordeum langei*), collected by Mrs. C. I. Sandwith in 1945 from Shirehampton.

Two other hybrids exhibited which are new to the British list were *Carex binervis* × *C. punctata* from rocks near Barmouth, shown by P. M. Benoit, and *Mentha aquatica* × *M. rotundifolia* (*M.* × *maximiliana*), collected by Miss B. M. Sturdy near Penzance, and shown by R. Graham. J. D. Lovis (University of Leeds) provided an interesting demonstration of ferns. *Asplenium adulterinum* is a tetraploid species ($2n = 144$), intermediate in morphology between *A. viride* and *A. trichomanes*, and is found on serpentine rocks in central Europe and Fenno-Scandinavia, where it usually grows with one or

A New Standard Cell by MUIRHEAD

£3.0.0

Post free in U K.

D-698 WESTON STANDARD CELL

This new cell combines the robustness and small size of our D-550 Miniature Standard Cell with a high capacity previously only obtainable in larger and more expensive types such as our D-402.

Whether you require a standard of E M F. for an industrial application or for laboratory use, this new cell will meet your needs and give many years of reliable service

SPECIFICATION

E.M F	1·01859V + 110μV − 90μV at 20°C.
Temperature coefficient	−0·00004 per °C.
Discharge rate	Up to 20μA for short periods
Internal resistance	600 ohms
Overall dimensions	$1\frac{15}{16}''$ x $1''$ x $3\frac{3}{8}''$
Weight	4 oz

Our D-550-A and D-402 Weston Standard Cells are still available

Advanced Level Examples in Physics

R V JOHNS, M A , B Sc

Lecturer in Physics and Mathematics, City of Liverpool College of Technology

W F WARE, B Sc , A Inst P

Senior Physics Master, Cathays High School for Boys, Cardiff

This book of numerical examples is designed to supplement the theoretical and laboratory work of students preparing for examinations in Physics at the Advanced level of the General Certificate of Education and for Intermediate Degree examinations Some 1,000 examples have been arranged by topics and carefully graded in difficulty Contents are arranged under the headings Mechanics and Properties of Matter, Heat, Light, Sound, and Magnetism and Electricity 16*s*

A Text-book of Electricity and Magnetism

E R NOAKES, M A , F Inst P

This is the new, Third Edition of a book which will meet the need of those taking Intermediate degree courses and the Advanced and Scholarship Examinations of the General Certificate of Education All the usual topics required at this stage are dealt with, and where necessary calculus is used Among the special topics discussed are the conduction of electricity through gases, atomic physics and modern views on ferro- and terrestrial magnetism *Third Edition* 14*s*

Science and its Background

H D ANTHONY, M A (Cantab), B Sc , Ph D (Lond), F R A S

Here is the story of science, with the background of history in which that story is set Although most of the chapters centre around individual men of science whose work is of value to day, the historical background is not only that of isolated biography but the continuous history of human affairs Two chapters, on post-war developments and the pursuit of science for its own sake, have been added for this second edition *Second Edition* 20*s*

Comprehensive Inorganic Chemistry

Edited by M CANNON SNEED, J LEWIS MAYNARD and ROBERT C BRASTED

Volume III—The Halogens, by ROBERT C BRASTED

Comprehensive Inorganic Chemistry is an eleven-volume reference work on the chemical elements and their inorganic compounds In this Third Volume the significant advances of recent years are fully reflected in a broad treatment of halogen chemistry Both basic principles and their applications are exhaustively covered, as well as the new processes, methods of production, and the chemistry of compounds which have lately become so important 35*s*

Petty Cury Cambridge

BASIC NAVAL ARCHITECTURE

K C BARNABY, O B E , B Sc , M I N A

(Second edition, revised and largely rewritten)

Now accepted as the standard work on naval architecture to serve as a comprehensive instruction to the whole subject Illustrated 35/–

BUILDING SPECIFICATIONS

T SUMNER SMITH, F S I , F I ARB

(Second edition, revised)

"A valuable textbook which takes the reader through every item of building work in its proper order "—*Master Builder* Illustrated 16/–

DICTIONARY OF PLASTICS

PAUL I SMITH

"A valuable supplementary to the published works on plastics "—*The Engineer* 15/-

DRY ROT AND OTHER TIMBER TROUBLES

W P K FINDLAY, D Sc

"Should find its place on the bookshelves of all who handle and use timber"—*Timber Technology* Illustrated 25/–

FROM ATOMS TO STARS

MARTIN DAVIDSON, D Sc , F R A S

(Third edition, revised and enlarged)

"The book is up to date and can be strongly recommended "—Sir H Spencer Jones, F R S (Astronomer Royal), in *Endeavour.* Illustrated 18/–

THE GRADUATE IN INDUSTRY

P DUNSHEATH, C B E , M A (CANTAB), D Sc (ENG), M Inst C E

(Past President of the Institution of Electrical Engineers)

(Second edition)

"Valuable information is given about possible openings in personnel and education work in industry"—*Engineering* 10/6

WAVES AND TIDES

R C H RUSSELL, M A , and Cdr D H MACMILLAN, R N R (retd)

(Second edition, revised)

"Theories and observations are admirably illustrated"—*The Navy* Illustrated 25/–

HUTCHINSON'S

RECENT SCIENTIFIC and TECHNICAL BOOKS

Volumes marked with an asterisk (*) have been received at "Nature" Office

Mathematics

BOAS, Jr, Ralph Philip Entire Functions (Pure and Applied Mathematics a Series of Monographs and Textbooks) Med 8vo Pp xi+276 (New York Academic Press, Inc, London Academic Books, Ltd, 1954) 6 dollars *

DEQUOY, N Mécanique à l'Usage de la Classe de Mathématiques Élémentaires (Traité de Physique Théorique et de Physique Mathématique —4) Super Royal 8vo Pp xii+200 (Paris Gauthier-Villars, 1954) 950 francs *

KAPLANSKY, Irving Infinite Abelian Groups (University of Michigan Publications in Mathematics—No 2) Med 8vo Pp v+91 (Ann Arbor University of Michigan Press, London Oxford University Press, 1954) 16*s* net *

SAVAGE, Leonard J The Foundations of Statistics (Wiley Publications in Statistics) Med 8vo Pp xv+294 (New York John Wiley and Sons, Inc London Chapman and Hall, Ltd, 1954) 48*s* net *

SOROKA, Walter W Analog Methods in Computation and Simulation, Med 8vo Pp xiii+390 (London McGraw-Hill Publishing Company, Ltd, 1954) 53*s* 6*d* *

Physics

GUMPRECHT, R O, and SLIEPCEVICH, C M Tables of Light-Scattering Functions of Spherical Particles Demy 8vo Pp 590 (Ann Arbor University of Michigan Press, London Oxford University Press, 1954) 52*s* net

NAKAYA, Ukichiro Snow Crystals Natural and Artificial Cr 4to Pp xii+510 (188 plates) (Cambridge, Mass Harvard University Press, London Oxford University Press, 1954) 80*s* net *

OLDENBERG, Otto Introduction to Atomic Physics Second edition Med 8vo Pp xiii+421 (London McGraw-Hill Publishing Company, Ltd, 1954) 48*s* *

RIDENOUR, Louis N Modern Physics for the Engineer Med 8vo Pp xix+499 London McGraw-Hill Publishing Company, Ltd, 1954) 53*s* 6*d* *

SOMMERFELD, Arnold Optics (Lectures on Theoretical Physics, Volume 4) Translated by Otto Laporte and Peter A Moldauer Med 8vo Pp xiii+383 (New York Academic Press, Inc, London Academic Books, Ltd, 1954) 6 80 dollars *

ter HAAR D Elements of Statistical Mechanics Med 8vo Pp xix+468 (New York Rinehart and Company, Inc, London Constable and Co, Ltd, 1954) 45*s* net *

Engineering

BANNER, E H W Electronic Measuring Instruments Med 8vo Pp xiv+395 (London Chapman and Hall, Ltd, 1954) 45*s* net *

KOTSCHIN, N J, KIBEL, I A, und ROSE, N W Theoretische Hydromechanik Band I Super Royal 8vo Pp xi+508 (Berlin Akademie-Verlag, 1954) 36 D marks *

LEVENS, A S Graphics in Engineering and Science 9½″×6½″ Pp 696 (New York John Wiley and Sons, Inc London Chapman and Hall, Ltd, 1954) 56*s* net

LYON, W V Transient Analysis of Alternating Current Machinery an Application of the Method of Symmetrical Components Med 8vo Pp 310 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1954) 56*s* net

OSGOOD, W R (edited by) Residual Stresses in Metals and Metal Construction Med 8vo Pp 363 (New York Reinhold Publishing Corporation, London Chapman and Hall, Ltd, 1954) 80*s* net

POPE, Alan Wind-Tunnel Testing Second edition Demy 8vo Pp xv+511 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1954) 68*s* net *

POWELL, Sheppard T Water Conditioning for Industry Med 8vo Pp x+548 (London McGraw-Hill Publishing Company, Ltd, 1954) 64*s* *

VER PLANCK, D W, and TEARE, B R Engineering Analysis an Introduction to Professional Method Med 8vo Pp 344 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1954) 48*s* net

von KÁRMÁN, Theodore Aerodynamics Selected Topics in the Light of Their Historical Development Med 8vo Pp x+203 (Ithaca, N Y Cornell University Press, London Oxford University Press, 1954) 38*s* net *

Chemistry Chemical Industry

ANGUS, L H Physical Chemistry (Advanced and Scholarship Levels) Demy 8vo Pp viii+392 (London University Tutorial Press, Ltd, 1954) 15*s* *

APPLEYARD, F N, and LYONS, C G Practical Pharmaceutical Chemistry Eighth edition Cr 8vo Pp 192 (London Sir Isaac Pitman and Sons, Ltd, 1954) 15*s* net

BELCHER, R, and GODBERT, A L Semi-micro Quantitative Organic Analysis Second, revised edition Demy 8vo Pp 222 (London Longmans, Green and Co, Ltd, 1954) 21*s* net

CHERONIS, Nicholas D With contributions by RONZIO, A R, and MA, T S Micro and Semimicro Methods (Technique of Organic Chemistry —Vol 6) Med 8vo Pp xxiii+628 (New York Interscience Publishers, Inc, London Interscience Publishers, Ltd, 1954) 12 dollars *

PERRY, John H (edited by) Chemical Business Handbook (McGraw-Hill Series in Chemical Engineering) Cr 4to Pp xiii+1328+31 (London McGraw-Hill Publishing Company, Ltd, 1954) 120*s* *

ROLLEFSON, G K (edited by), POWELL, R E (in association with) Annual Review of Physical Chemistry Volume 5, 1954 Med 8vo Pp x+540 (Stanford, Calif Annual Reviews, Inc, 1954) 7 dollars *

SPRINGALL, H D The Structural Chemistry of Proteins Demy 8vo Pp x+376 (London Butterworths Scientific Publications, New York Academic Press, Inc, 1954) 45*s* net *

Technology

ANDERSEN, A J C Margarine Royal 8vo Pp viii+327 (London Pergamon Press, Ltd, 1954) 63*s* net *

DAVIES, C N Dust is Dangerous Demy 8vo Pp xviii+116+30 plates (London Faber and Faber, Ltd, 1954) 21*s* net *

DENNIS, W H Metallurgy of the Non-Ferrous Metals Demy 8vo Pp xii+647 (London Sir Isaac Pitman and Sons, Ltd, 1954) 70*s* net

MORGAN, P (edited by) Glass Reinforced Plastics Royal 8vo Pp 256 (London Iliffe and Sons, Ltd, 1954) 35*s* net

PARKER, Milton E, with the collaboration of HARVEY, Ellery H, and the late STATELER, E S Elements of Food Engineering Volume 2 Unit Operations—1 Pp vi+360 68*s* net Volume 3 Unit Operations —2 Pp vi+241 54*s* net (New York Reinhold Publishing Corporation, London Chapman and Hall, Ltd, 1954)*

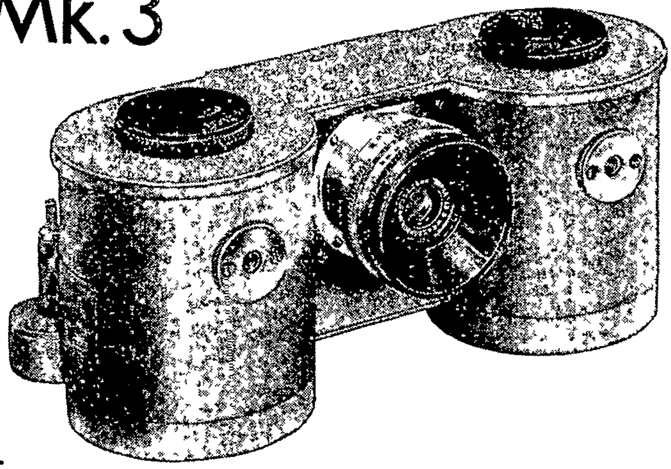
The Auto Camera Mk. 3

A VERSATILE RECORDING INSTRUMENT



Specially designed to cover a wide field of industrial and scientific work where the rapid production of high quality microfilms is required It is eminently suitable for such purposes as instrument recording, photo-micrography, oscillograph records, process timing, document copying, etc It is fully automatic in its operation, the exposure and film transport being effected by a single electrical impulse operating on 12 or 24 volt d c Special daylight loading cassettes give a full 200 1″ × 1″ or 300 1″ × ¾″ exposures from one loading of 35 mm perforated film. The camera may also be controlled by manual operation

Write for 16-page illustrated brochure.

THE INSTRUMENT DIVISION OF

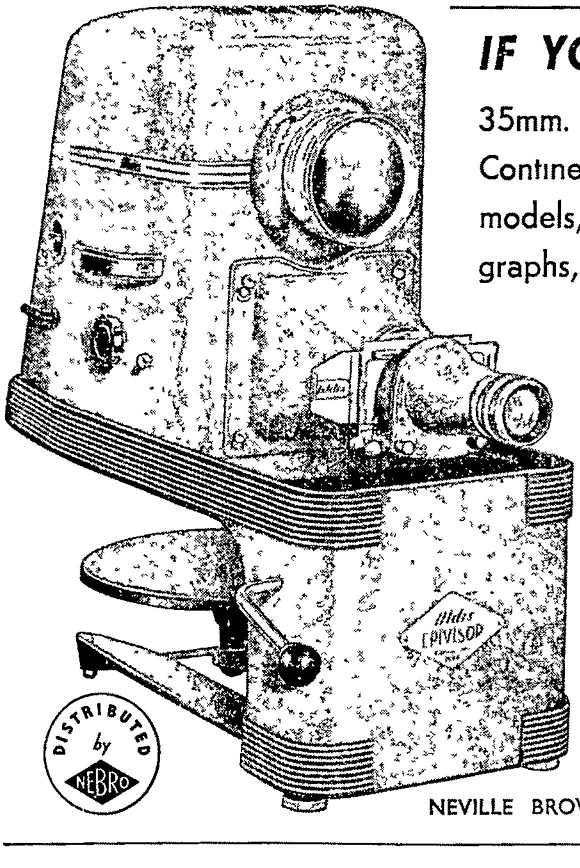
Sales and Service in all principal centres



IF YOU WANT TO PROJECT

35mm. film strips, 2″x 2″ or 3¼″x 3¼″ slides, Continental slides, micro slides, specimens, models, drawings, blueprints, photographs, graphs, etc, etc. . .

THERE IS ONLY ONE ANSWER

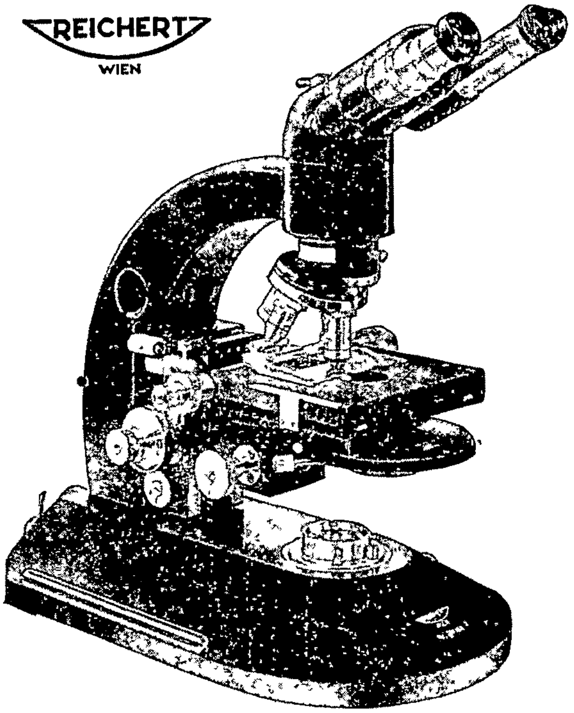
Aldis 'EPIVISOR'

(Registered Trade Mark)

EPIDIASCOPE

This versatile instrument enables you to project greatly enlarged and perfectly defined images of flat and solid objects, as well as film strips and slides It is indispensable in research and in training Full details will gladly be sent on request, together with the name of your nearest dealer, who will be pleased to demonstrate

Sole Wholesale Distributors
NEVILLE BROWN & CO LTD, 77 NEWMAN ST, LONDON, W 1



REICHERT NEOZET

well worth looking into

We have no hesitation in saying that this instrument represents the most important advance in routine microscopy for many years Here are some of its features

Automatic Coarse Focusing greatly speeds up routine high power microscopy and positively prevents damage to slides and lenses

Built-in Illumination with lever operated lamp condenser and field iris diaphragm for Koehler illumination

Novel Binocular Body with constant tube length and integral **magnification changer.**

Anoptral Contrast Equipment opens up new vistas in the examination of unstained specimens by greatly increased contrast combined with maximum resolution and freedom from reflections *

Polyphos Universal Condenser provides bright ground, phase- or anoptral contrast and dark ground illumination in continuous succession

We shall be pleased to send you further particulars of this remarkable microscope and to demonstrate it to you in our showroom

* The Anoptral Contrast Equipment is now available for fitting to your existing microscopes

SINGER

Micromanipulators

Singer (High-power) Micromanipulators are suitable for use under magnifications of from × 100 to × 1,000 diameters *plus*, as described by Barer and Saunders-Singer in the *Quarterly Journal of Microscopical Science*, Vol 89, pp. 439-447, December, 1948.

Singer Microdissectors (Low-power Micromanipulators) are suitable for use under magnifications of from 1 to ×200 diameters and are described by Barer and Saunders-Singer in the *Journal of Scientific Instruments*, Vol 28, pp 65-68, March 1951

FOR pH CONTROL

JOHNSONS OF HENDON offer to chemists and manufacturers this useful series of five test papers for the measurement of pH values. UNIVERSAL is one paper covering completely the range from pH 1 to pH 10, enabling pH values to be checked to within 0 5 pH COMPARATOR test papers make a set of four separate indicators for obtaining still greater accuracy by determining the pH value of any solution to within 0 3 pH

Descriptive leaflet will be sent free on request

New Spekker Fluorimeter

The increasing use of fluorescence methods for micro-analysis, for instance in the determination of anti-malarials excreted in the course of treatment, has rendered obsolete the earlier forms of fluorimeter which were capable of only relatively insensitive measurements.

The new Spekker Fluorimeter, while retaining its well-established optical principles, has been redesigned to meet the demand for an instrument providing the very high sensitivity and accuracy necessary for this type of work.

It is a compact instrument, simple to operate from A.C. mains. The balanced photoelectric system compensates for any fluctuations in intensity of the light source due to mains voltage variations, thus ensuring permanent accuracy of calibration.

The instrument can be readily converted to the well-known Spekker Absorptiometer; and parts can be supplied to owners of the Absorptiometer which will convert it to the new type Fluorimeter.

For full information please write for catalogue CH390 (N.1)

other of the species mentioned It may yet be found on serpentine rocks in the more remote parts of Scotland Investigation showed that it is amphidiploid, with the diploid form of *A. trichomanes* ($2n = 72$) and *A viride* ($2n = 72$) as its probable parents The hybrids *A. trichomanes* ($2x$) × *A adulterinum*, *A adulterinum* × *A trichomanes* and *A viride* × *A. adulterinum* have been synthesized *Asplenium* × *breynii*[1] was also exhibited.

Another aspect of the importance of the study of hybridity was demonstrated in the exhibit by Prof T G Tutin (University College, Leicester) of British material of *Symphytum.* The plant usually referred to as *S peregrinum*, which is frequent, and very variable, appears to be the central part of a hybrid swarm from the cross between *S officinale* and *S asperum* Dr. E F. Warburg (Department of Botany, University of Oxford), who has been re-examining material of alleged hybrids in connexion with work on the new "Plant List" which the Society has in preparation, exhibited herbarium specimens of some of the plants on which published names have been based He found that some of these 'hybrids' are morphologically convincing, but others, such as *Lotus* × *davyae* and *Potentilla* × *cryeri*, are apparently only forms of one of the alleged parents

The University of Manchester exhibit on *Senecio* covered an excellent example of a polyploid hybrid which is fertile, and this is to be described as a new species *Senecio squalidus* ($2n = 20$) was crossed with *S vulgaris* ($2n = 40$), and from the hybrid ($2n = 30$), by colchicine treatment, the synthetic polyploid ($2n = 60$) was produced. This was exhibited in three forms mid-ray, long-ray and rayless. The synthesized plant was found to agree in morphological characters with a natural polyploid found in North Wales by H E Green in 1948, which was seen wild in quantity again this year, and which has persisted in cultivation since its discovery A technique for growing species of *Euphrasia*[1], which are partially parasitic, was demonstrated last year by P F Yeo (University of Cambridge) This year he exhibited artificial hybrids of *Euphrasia occidentalis* with *E salisburgensis* var *hibernica* and with *E pseudokerneri*, which had been grown with their parents on *Medicago lupulina* as the standard host

In 1952, *Artemisia norvegica* was discovered in north-west Scotland[2] Critical examination by Prof E Hultén of the circumpolar group of closely related species to which this belongs has shown that the plant from Scotland is distinct, and it has been described as ssp *scotica*[3]. The type material on which the new taxon is based was exhibited by the Department of Botany, British Museum (Natural History). The Department also showed specimens of *Rubus arcticus* from its collection labelled as collected from Ben Lomond and "Ben-y-glo", for comparison with one from "Ben Lawers, 1837" recently detected in Cosmo Melville's herbarium in the Butler Museum, Harrow, by R M Harley This circumpolar species occurs in Scandinavia, and further search may well confirm it as a British plant The Museum also exhibited interesting sheets of *Carex lepidocarpa* ssp *scotica*[4], *Nuphar pumila* and *N. intermedia*[5], and viviparous grasses[6] to illustrated recent papers in *Watsonia.* P. S. Green (Royal Botanic Gardens, Edinburgh) showed seeds, specimens and a map of the distribution of *Stellaria nemorum* spp *glochidisperma*, which he has recently described for Britain[7].

Dr S. M. Walters (Botany School, University of Cambridge) demonstrated the use of the category 'sub-species' in taxonomy, pointing out that in current practice three different situations are involved, namely, the geographical sub-species, the "cyto-sub-species" and the "ignorance sub-species". He suggested that the use of the same category for genetically different situations is in no way either inconvenient or undesirable, and illustrated the point with reference to the diploid, tetraploid and hexaploid cytodemes of *Polypodium vulgare* L , for which he advocated a sub-specific category Dr. K B. Blackburn and Miss A W. Adams (King's College, Newcastle upon Tyne) provided an interesting exhibit of cytology of *Herniaria* In the *glabra* group of the sub-genus *Eu-herniaria* the chromosome numbers show a polyploid series on a base of nine. S Challenger (University of Bristol) exhibited flowers of *Dianthus gratianopolitanus* from Cheddar Gorge, which show a surprising amount of variation for a species with such a restricted distribution in Britain. Living plants, silhouettes of the fruit papillæ and distribution maps of *Galium pumilum* in Britain were shown by K M Goodway, who suggested that this could be tentatively divided into western ($2x$), montane (? hybrid), northern-limestone ($4x$), southern-chalk (? $8x$) and Cheddar (? $8x$) forms D. J Hambler (Queen Mary College, London) illustrated the cytology and ecology of Orobanchaceae and semi-parasitic members of the Scrophulariaceae[8], A C Jermy (University College, Leicester) showed variations in *Carex nigra* and its hybrids, and M C F. Proctor (Nature Conservancy) of *Helianthemum canum*

The main exhibit concerned with the distribution of British plants was that of the Society's distribution-maps scheme[9], on which three full-time and two part-time assistants are now engaged in addition to the director. The nine hundred 10-kilometre squares for which volunteers have already accepted responsibility for the contribution of records were indicated on a large map, and further offers were received during the exhibition Dr C D Pigott (University of Sheffield) provided an exhibit to illustrate the fact that many northern plants reach the south-eastern limits of their distribution, and many southern plants their north-western limits, along a line that runs diagonally across central England, and used *Asplenium viride* and *Cirsium acaule* as examples These meet but never overlap, and it is significant that near Sheffield the reproductive capacity of *C acaule* is greatly reduced There seems little doubt that this phytogeographical boundary is also a significant climatic boundary J E Lousley showed photographs of the very rare orchid *Epipogium aphyllum* from a new locality in Oxfordshire Dr T D V. Swinscow exhibited photographs of ferns at Leagrave Station, Bedfordshire, where nine species had been found They included both calcicole and calcifuge ferns, and their occurrence on a railway platform suggests that distribution of the spores may be facilitated by the traffic R A Graham provided evidence that *Cypripedium calceolus* occurred in Yorkshire in 1954 P M Benoit showed *Salicornia perennis* from Barmouth and Mochras, Merioneth, as the first certain records for Wales W. S. Lacey (University College of North Wales, Bangor) had an exhibit to illustrate his discovery of *Orchis traunsteineri* in Caernarvonshire. Sub-fossil botany was represented by an exhibit by J W Franks (University College, Leicester) of plants from the '*N*' horizon in the Esthwaite basin The drop in tree pollen, rise in grass pollen and occurrence of *Plantago lanceolata* suggest that this horizon may represent the beginnings of cultivation in the area.

A useful warning to modern collectors and commentators was implied in the exhibit by Mrs H N Clokie (Department of Botany, University of Oxford) of selected sheets from the Du Bois (1690–1723) and Sherardian (1700–26) herbaria These showed the confusion and loss of information which can result from illegible labels, or from mounting plants which could not be certainly associated with their labels The Library of the British Museum (Natural History) displayed a magnificent series of unpublished drawings prepared for Church's "Types of Floral Mechanism" and unpublished text The view was freely expressed that the publication of these fine additional drawings would be a valuable addition to the book already available

A full account of the exhibits will appear in due course in the *Proceedings* of the Society The meeting was attended by about two hundred and eighty members and guests J. E Lousley

HYDRAULIC TRANSPORT OF COAL

TRANSPORT of coal from the mines to the user represents an appreciable proportion of the energy in the fuel Normally this is done by rail or sea transport, but transportation through pipes as a suspension in water is another possibility. The advantages of hydraulic transport over short distances within the workings of the colliery are apparent—either underground or on the surface, or even as an alternative to normal cage winding There is, however, the possibility that hydraulic transport of coal could be operated over much longer distances, this has already been accomplished up to five miles, and a hundred-mile pipe-line is planned in the Pittsburgh area These advantages and many others were described by Dr Idris Jones, director-general of research, National Coal Board, in an introductory address to a colloquium on "The Hydraulic Transport of Coal" held by the National Coal Board in London during November 5–6, 1952 (pp vi+75 London National Coal Board, 1954), which was opened by Sir Charles Ellis

Although there is in existence much experimental data on the transport of solid material by water streams in open channels and pipes, the numerous factors involved have hindered the formulation of any theory which will give a full understanding of the transport process in pipes The purpose of the colloquium was to assemble and compare such results as are available and to discuss tentative theories The first four papers dealt mainly with fundamental theory and the development of dimensionless groups characterizing the flow of suspensions through pipes, with lump sizes up to 4 in Some of the authors admitted that the present theory is inadequate, and it is evident that this is only the beginning of research on this subject The second group of four papers described the development of coal feeders and experimental installations in France and at Markham Colliery

The discussion on the papers is included in the publication, and the proceedings form a useful basis for further study of a subject which is becoming of increasing practical importance. H Heywood

RECENT WORK IN MAYAN ARCHÆOLOGY

OVER a long period of years, the Carnegie Institution, through its Archæological Department, has produced a most valuable series of publications, most of which deal with the Maya area The shorter studies in this series have appeared in volumes of *Contributions*, of which that under review is a useful example*

No 52, by Howel Williams, deals with some human and animal footprints first discovered seventy years ago on the outskirts of Managua, Nicaragua, which aroused a great deal of interest when they were found, owing to their supposedly great age This was based on the considerable depth of four metres at which they were found, and was estimated at 50,000 years or more Further examples were found at the same horizon in 1941, so it has been possible to study the question afresh Williams shows that the deposits in and under which they occur are pumices and mud-flows associated with vulcanicity, which must have been accumulated at a great rate, so that their age has been grossly exaggerated. The prints are abundant and may well have been made by people fleeing from a rain of ash from the volcano Masaya On the scanty evidence of a sheard of Usulutan ware found on the site at a considerably higher level, it is concluded that the footprints are between 3,000 and 5,000 years old The author holds out little hope of obtaining material for radiocarbon dating, so it is unlikely that this estimate can be improved on

The second paper, No 53, by A V. Kidder and E M Shook, describes the partial excavation of a complex temple mound containing at least two important burials at the Maya site of Kaminaljuyú, near Guatemala City The authors, with J D Jennings, have already published an important work on Kaminaljuyú, but it is a very large site and a great deal remains to be done This was largely a rescue dig, necessitated by the destruction of part of the mound by brick-making activities The mound proved to belong to the Miraflores phase of the Pre-Classic or Middle Culture Period, dating in all probability from the first part of the first millennium B C, the authors had suspected that this might be so, but had been loth, in the absence of positive proof, to ascribe so large and complex a structure to this early period The importance of the work lies mainly in the recognition of this fact, which may make it necessary to postulate the emergence of 'Classic' social structures, for example, a ruling class, in pre-Classic times, and perhaps to revise our chronological nomenclature accordingly

Something is known of the archæological record of the Maya in Northern Yucatan from the Formative

---

* Contributions to American Anthropology and History Vol 11, Nos 52–56 (Publication 596) Pp vi+236 (Washington, D C Carnegie Institution of Washington, 1954) 6 75 dollars, paper, 7 50 dollars, cloth

Period, before, say, the fourth century A.D., down to the fall of the city of Mayapan about a century before the Spanish conquest; but after that there is a gap which is difficult to explain, just when traditions begin to throw some light on Maya history. In No. 54, R. L. Roys studies the Spanish Colonial sites, particularly the churches and convents, in this area and their relations with Maya ruins, in the light of his intimate knowledge of the country and the documentary sources. He concludes, not only that many Colonial towns and villages were on pre-Conquest sites, but also that the churches and plazas generally occupy the old ceremonial centres. This fact, and the destruction of the old buildings to provide materials for the new, are largely responsible for the gap in the archæological record, and it should now be possible to fill it by exploring suitable post-Conquest sites.

In No. 55, G. Stromsvik describes three superimposed ball-courts at the famous Classic Maya site of Copan, Honduras, together with comparable examples elsewhere. The courts are structures enclosed by lateral walls for playing a team game with a rubber ball, which in one form or another was widespread in middle America in ancient times, and which still survives on flat courts in remote parts of Mexico. It is possible that the first court at Copan, perhaps dating from the fifth century A.D., is the oldest yet discovered, and the latest may date from late in the eighth century. The latter is remarkable for the presence of three stone macaw heads tenoned into each side of the lateral structures; these may be related to the stone rings which formed a kind of goal in later courts. A feature of the report is a reconstruction drawing of the latest court and its surroundings by Miss Tatiana Proskouriakoff.

No. 56, by R. E. Smith, is a short paper describing pottery, believed to be of late Classic date, from a rubbish pit in Alta Verapaz in Guatemala. It is rather a specialized subject, and its importance lies in the fact that the archæology of Alta Verapaz is very little known.

G. H. S. BUSHNELL

EFFECT OF STREPTOMYCIN ON VARIOUS ENZYMES RESPONSIBLE FOR SYNTHESES AND DEGRADATIONS OF HIGHER SACCHARIDES

By DR. S. A. BARKER, DR. E. J. BOURNE, PROF. M. STACEY, F.R.S., and R. B. WARD
Chemistry Department, University of Birmingham

PREVIOUS workers have shown streptomycin to affect certain enzyme systems, its inhibition of the oxalacetate–pyruvate condensation[1] being particularly important. However, little has been reported of its influence on enzymes responsible for the synthesis and degradation of oligo- and polysaccharides, and this formed the subject of the investigation now described. It was considered that streptomycin might exert part of its powerful antibiotic action against mycobacteria by blocking some of the enzyme systems which build up their complex polysaccharide molecules. Such a hypothesis is particularly attractive in the case of *Mycobacterium tuberculosis*, since certain of the specific polysaccharides of this organism and the antibiotic show structural similarities, inasmuch as they are both glycosides with furanose and glucosamine components (D-arabofuranose with D-glucosamine[2] and streptofuranose with N-methyl-L-glucosamine, respectively). Furthermore, since streptomycin is mainly of a carbohydrate nature, it was felt that it might serve as either a donor or a receptor in suitable transglycosylation reactions[3] and give rise to modified streptomycins; if this happened, it could account for the relative ease with which mycobacteria can adapt themselves to streptomycin.

In order to test these theories, each enzyme solution was incubated with the appropriate substrate, in the presence and absence of streptomycin sulphate (0–15 per cent), the two digests being adjusted to the same *p*H to counteract the acidity of the antibiotic salt. At intervals, the digests were analysed for sugars by paper chromatography using (*a*) the organic phase of a butanol (40 per cent) – ethanol (10 per cent) – water (49 per cent) – ammonia (1 per cent) mixture as the solvent, with aniline hydrogen phthalate[4] and naphtharesorcinol[5] detector sprays, or (*b*) the benzylamine method[6], with ninhydrin as the detector. In addition, each sample was examined in 0·2 N acetate buffer (*p*H 5·0) on four identical ionophoretograms (600 V., 4 hr.), which were developed, severally, with aniline hydrogen phthalate[4,7], naphtharesorcinol[5], a modified Elson–Morgan reagent, and alkaline diacetyl/α-naphthol[7].

Although no evidence was obtained with the enzymes studied of a streptomycinase, or of a transglycosylation giving rise to a compound analogous to the naturally occurring mannosyl streptomycin, several interesting effects were observed, as follows.

Invertases and transfructosylases[8]. Commercial yeast 'invertase' (British Drug Houses, Ltd.), acting on sucrose, gave fructose, glucose, di- and tri-saccharides. In the presence of streptomycin sulphate (15 per cent), the reaction was retarded, particularly as regards the formation of the higher saccharides. With the 'invertase' of *Aspergillus niger* (strain 152 [9]), used as a cell-free extract from a culture grown on sucrose, the effect of streptomycin sulphate was even more apparent. Whereas the enzyme normally converts sucrose into glucose, fructose and higher saccharides, the presence of streptomycin sulphate in concentrations of 0·01 per cent and higher caused a marked inhibition of fructose formation and prolonged the life of the higher saccharides. A possible explanation of these phenomena is that invertase- and transfructosylase-activities are not always exhibited by a single enzyme, as is widely believed (cf. ref. 8), but that there may be two distinct enzymes, one of which is more sensitive to streptomycin than the other; further work to test this hypothesis is envisaged.

Nigeran synthesis. The addition of streptomycin sulphate (10 per cent) to the sucrose (10 per cent) – mineral medium used to culture *Aspergillus niger* (strain 152), and also a related strain, caused marked increases (ten- and three-fold, respectively) in the percentages of nigeran[10] in the dried mycelia. Smaller concentrations of streptomycin sulphate had correspondingly smaller effects.

Panose synthesis. A cell-free extract of *Aspergillus niger* (strain 152) produced, *inter alia*, glucose, *iso*-

maltose and panose when incubated with maltose[11]. In the presence of streptomycin sulphate, at concentrations greater than 0 1 per cent, the formation of *iso*maltose and panose was retarded

Amylomaltase. A cell-free extract of *Escherichia coli* (Monod strain) which had been cultured on maltose, when incubated with maltose, produced glucose, fructose, maltotriose, maltotetraose, etc [12]. In the presence of streptomycin sulphate (15 per cent) the formation of fructose, which arises from enzymes other than amylomaltase, was markedly reduced

Other enzyme systems Five other enzymic processes were found to be inhibited slightly by streptomycin sulphate (15 per cent), they were (*a*) dextran synthesis from sucrose by the dextransucrase of *Betacoccus arabinosaceous*, (*b*) oligosaccharide synthesis from lactose by the transgalactosylase of *Aspergillus niger* (strain 152), (*c*) oligosaccharide synthesis from cellobiose by almond emulsin[13], (*d*) the hydrolysis of amylose by salivary α-amylase, and (*e*) the hydrolysis of amylose by soya bean β-amylase[14]. There was no detectable effect of the antibiotic (15 per cent) on (*a*) the liberation of phosphate from dipotassium α-D-glucose-1 phosphate by phosphorylase, (*b*) oligosaccharide synthesis from cellobiose by *Aspergillus niger* extracts[15], or (*c*) phosphate liberation from α-glycerophosphoric acid and dipotassium α-D-glucose-1 phosphate by bovine intestinal phosphatase

Thus it will be seen that streptomycin has a modifying effect on some of the enzyme systems concerned with the synthesis of higher saccharides, and a more detailed study of these is being made

We are indebted to the Glaxo Laboratories, Ltd, for the generous provision of streptomycin sulphate and for financial assistance. [Nov. 24.

EXCHANGE REACTIONS IN THE ENTRY OF CATIONS INTO PLANT TISSUES

By R SCOTT RUSSELL and M J AYLAND

Department of Agriculture, University of Oxford

IT is well established that when actively metabolizing plant roots or tissue slices are transferred to solutions containing higher concentrations of ions than those to which they were previously exposed, a rapid entry of ions occurs, but within a few minutes the rate of entry decreases Conversely, when tissues are transferred to more dilute solutions an initial rapid outflow is observed[1,2]. Conflicting interpretations of this initial flux have been advanced. It has been widely held that exchange reactions or adsorption at the cell surface are the first step in ionic entry[3-6]. Evidence that the rate of absorption is not controlled by diffusion into the tissues accords with this view[7] Recently, however, Hope and Stevens[2], and following them, Butler[1], have regarded the initial flux as a diffusion process In his later work, Hope has suggested that non-diffusible anions influence the rate of absorption, but he has retained his earlier concept that ions diffuse into the "apparent free space" of tissues

The use of radioactive isotopes makes it a simple matter to study the competition of ions for entry into tissues over short intervals, and the relative importance of exchange and diffusion processes can in this way be examined If diffusion is the rate-limiting process, the entry of one cation will not be affected by the presence of another cation in low concentration However, if the presence of sites on which exchange or adsorption occurs is the controlling factor, inter-ionic competition is to be expected even in the shortest experimental periods Experiments of this type have been conducted using washed carrot disks, detached barley roots and intact barley plants In Table 1, representative results are shown for the absorption, over periods of 5–20 minutes, of labelled rubidium and cæsium in the presence and absence of other monovalent cations Even in five minutes the absorption of the labelled ion is markedly reduced by the presence of other monovalent ions The percentage reduction changes little if the experimental period is increased to twenty minutes These results are interpreted as indicating that diffusion is not a significant factor determining the rate of the initial entry of ions into the tissues studied, it is assumed that the process depends on exchange reactions at or near the cell surface. The mechanism is, however, not ‘ passive” in the sense that Broyer[3] has used that word to denote processes independent of metabolism. It has been found that the initial inward flux can be reduced by 2 4-dinitrophenol and by sodium azide at 25° C (Table 2) In work with the latter substance it has been demonstrated that the observed effect was not due to the sodium ions in

* Administered for 30 minutes immediately before absorption period

sodium azide Other aspects of these studies will be discussed elsewhere

In experiments with intact plants it has been possible to demonstrate ionic interactions in other phases of the absorption process[9] In experimental periods of four hours it has been found that the interaction of potassium with rubidium is different with respect to (*a*) the absorption of rubidium, and (*b*) its transference to the shoots. Moreover, the nature of these interactions is dependent on the initial nutrient status of the plants (Table 3) These results indicate that the two ions must interact in at least two distinct phases of the absorption process, namely, the initial entry into the roots and in the mechanism whereby ions are transferred across the symplast to the stele The complexity of the processes in which ions compete is further indicated by a number of other results which will be discussed more fully elsewhere (*a*) Competition affects not only the initial inward movement of ions (cf Table 1) but also their rate of exchange when the tissues are transferred to unlabelled solutions. (*b*) When equivalent concentrations of rubidium and cæsium are administered for five minutes it is found that rubidium is more effective than cæsium in inhibiting the entry of the other ion—a result contrary to that obtained with inert exchange systems

It is concluded, therefore, that the process of ionic accumulation is considerably more complex than that envisaged by Jacobsen and Overstreet[5], who postulated a single exchange step for ions of either sign whereby they are bound to carrier molecules which transfer them across the cytoplasm No evidence as yet available, however, appears to conflict with the view that reactions of the type they envisage may occur after the initial entry of ions by exchange into the tissues For reasons discussed elsewhere[9], this hypothesis is attractive, but it is, as yet, unsupported either by the identification of the carrier or by evidence as to the manner whereby ions are bound on the carrier Epstein[4] has endeavoured to examine the latter question by a kinetic study of the interaction of ions for entry into tissues If the conclusions here presented are correct, his interpretation is unwarranted since ions interact for sites unconnected with the mechanism which is responsible for their transference across the cytoplasm Moreover, the manner in which he analysed his results appears open to question He employed the procedure developed by Lineweaver and Burk[8] for enzymatic studies For this procedure to be applicable to salt uptake, a linear relationship must exist between the reciprocal of the rate of absorption and the reciprocal of the external concentration Epstein demonstrated the linearity of this relationship for the absorption of rubidium from solutions of concentrations 2–50 milli-equivalents per litre In the present work, however, a concentration-range extending down to 0 1 milli-equivalents per litre was used with carrot disks under similar conditions and it was found that the relationship was not linear over this wider concentration range The results of an experiment using cæsium at concentrations 0 1–12 8 milli-equivalents per litre are shown in Fig 1 Similar results were obtained with rubidium It is apparent from Fig 1 that a linear relationship might have been inferred from the results which lie within the range employed by Epstein Thus it must be concluded that theoretical interpretations based on such data are likely to be misleading until the steps in the overall process of ionic absorption are more fully elucidated

Analgesic and Antipyretic Activities of 4-Hydroxy*iso*phthalic Acid

4-HYDROXY*iso*PHTHALIC acid is a by-product of the manufacture of salicylic acid by the Kolbe–Schmitt reaction and has been found to be a major constituent of the 'brown dust' residues from the sublimation process for the purification of salicylic acid[1] Analysis of a typical sample of 'brown dust' showed it to contain 10 per cent of salicylic, 82 per cent of 4-hydroxy*iso*phthalic and 3 per cent of 2-hydroxy*iso*phthalic acids, together with some inorganic material From this source there is thus potentially available a considerable quantity of 4-hydroxy*iso*phthalic acid, the chemistry of which is being investigated as part of a research programme on the Kolbe–Schmitt reaction at the Chemical Research Laboratory[2] From a consideration of its structural similarity to salicylic acid, it was suggested at the Chemical Research Laboratory that 4-hydroxy*iso*phthalic acid might also possess similar pharmacological properties Accordingly, in February 1954, a pharmacological investigation was initiated at Ware and, since the findings were favourable, biochemical studies were also undertaken

In the initial experiments, drugs were administered by the intraperitoneal route, aspirin and phthalic acid derivatives being suspended in 5 per cent gum acacia In analgesic tests, a simplified form of the analgesiometer of Green, Young and Godfrey[3] was used, which measures responses in terms of the pressure, applied to the tip of the tail, required to elicit a squeak from a young rat This method showed that 4-hydroxy*iso*phthalic acid undoubtedly possesses analgesic properties, its median effective dose being 303 (limits 261–353) mgm per kgm In comparative tests it exhibited 4 1 (limits 3 2–5 5) per cent of the activity of codeine The median lethal dose (*LD*50) for young rats was 1,071 (limits 968–1,185) mgm per kgm, and a dose of 600 mgm per kgm. was tolerated by all eighty-seven rats which received it Comparison of the *LD*50 of 4-hydroxy*iso*phthalic acid with the corresponding published figures for codeine[4] indicates that it possesses about 10 per cent of the toxicity of codeine Compared with 4-hydroxy*iso*phthalic acid aspirin was both more toxic and less effective The *LD*50 was 541 (limits 485–603) mgm per kgm, and a dose of 300 mgm per kgm, which was tolerated by all rats, failed to show any analgesic effect, although higher doses appeared to do so

In comparative tests of antipyretic activity in rabbits, it was found that 4-hydroxy*iso*phthalic acid was about as effective as aspirin in counteracting fevers caused by a preparation of pyrogen from *Proteus vulgaris*

Since 4-hydroxy*iso*phthalic acid promised to have clinical value of a type similar to, but greater than, aspirin, a chronic toxicity test was carried out by administering the drug at 0 5 and 1 0 per cent in the diet to mice for a period of fourteen weeks In this experiment, it exhibited very low toxicity, of the same order as that of aspirin, which was used for reference

Analgesic tests were also performed with 2-hydroxy*iso*phthalic, phthalic, *ter*ephthalic and *iso*phthalic acids The 2-hydroxy acid was about equipotent to the 4-hydroxy, while the unsubstituted acids showed slight activity

Preliminary investigations on the excretion of 4-hydroxy*iso*phthalic acid by rats showed that within 24 hr about 40 per cent of a 10-mgm dose given by stomach tube was excreted unchanged in the urine and about 25 per cent in the fæces The method of estimation was based on the reddish-purple colour formed when the acid is allowed to react with ferric nitrate Acid hydrolysis failed to increase the amount of free 4-hydroxy*iso*phthalic acid, suggesting the absence of certain conjugated forms from the urine, while the absence of other possible metabolites, such as salicylic, *p*-hydroxybenzoic and gentisic acids, was demonstrated by means of paper electrophoresis

Clinical trials to investigate the possible therapeutic applications of these findings are in progress

The 'brown dust' was kindly supplied by Monsanto Chemicals, Ltd We wish to thank the directors of Allen and Hanburys, Ltd, and the director of the Chemical Research Laboratory, Teddington, for permission to publish this work.

Imidazole Complexes of Myoglobin and the Position of the Hæm Group

WE have prepared complexes of imidazole, 1-methyl imidazole and 4-methyl imidazole with various species of myoglobin, and crystallized them in forms previously described[1], the X-ray diffraction patterns of the crystals were then compared with those obtained from corresponding forms of met-myoglobin crystals The results, which were similar for all three imidazoles, are summarized in Table 1 (In each case a large excess of imidazole was used without this precaution combination is always incomplete)

Table 1

Species	Form		*a*	*b*	*c*	*β*	Intensities
Sperm-whale (ammon sulphate)	Met- Imid-	*A* *A*	64 6 A 64 4	31 1 A 30 7	34 8 A 34 7	105 5° 105 5°	Scarcely changed
Sperm-whale (phosphate)	Met- Imid-	*B* *B*	48 9 48 8	40 2 40 3	79 3 78 5		Considerable changes
Gentoo penguin (ammon sulphate)	Met- Imid-	 *I*	(no crystals formed) 94 5	 38 3	 43 5		
Gentoo penguin (phosphate)	Met- Imid-	*G* *H*	48 3 106 4	80 2 39 1	78 5 45 3		

Three types of behaviour have been observed. (a) In sperm-whale monoclinic crystals (type *A*), the imidazole derivative is nearly isomorphous with the metmyoglobin. The cell dimensions are virtually unaltered, if anything slightly decreased; the intensities are scarcely changed, the differences being of the same order of magnitude as those between carbonmonoxy- and met-myoglobin crystals. (b) In sperm-whale orthorhombic crystals (type *B*), the imidazole derivative has again nearly the same cell dimensions as the metmyoglobin, but the intensities are very substantially changed, and are appreciably different in the different imidazole derivatives. (c) In gentoo penguin myoglobin, either grown in ammonium sulphate or in phosphate, the addition of an imidazole group produces a radical change in crystal packing. In ammonium sulphate the metmyoglobin will not crystallize at all, whereas the imidazole derivative gives orthorhombic crystals of type I ($P2_12_12_1$, 4 mol./cell); in phosphate the metmyoglobin gives the face-centred type *G* ($C222_1$, 8 mol./cell), while the imidazole derivative gives the orthorhombic type *H* ($P2_12_12_1$, 4 mol./cell).

These results give some indications about the location of the hæm group in myoglobin. Broadly, we can imagine three main types of site for the group: (i) embedded deeply inside the molecule; (ii) on the side of a wide cleft or groove; and (iii) on the surface. In case (i) the attachment of a substantial group such as methyl-imidazole (which is a roughly circular disk of dimensions about 7 A. × 3.7 A., by no means negligible in comparison with the molecule of myoglobin itself which, if spherical, would have a diameter of about 32 A.) should change the dimensions of the molecule and appreciably increase at least some of the cell dimensions in all the crystal forms; in case (ii) a group attached to the hæm would exert no steric effects at all and imidazole crystals would be isomorphous with metmyoglobin crystals in all forms. On the other hand, in case (iii) one would anticipate that in some forms of crystal the hæm group would be distant from points of contact between molecules, and no changes in structure would be produced by attachment of imidazole to it (as observed in sperm-whale monoclinic crystals); whereas in others the imidazole group attached to hæm would be near a point of contact and would cause appreciable distortions in packing (as in sperm-whale orthorhombic crystals) or would even impose a completely new type of packing (as in penguin crystals).

Hence it appears to us very probable that the hæm group is located on the surface of the myoglobin, though it must be realized that any conclusion is bound to be tentative, partly because it is easy to imagine various configurations of the molecule intermediate between the three extremes defined above, partly because it is not certain (though it is very likely) that the molecule of penguin myoglobin has a structure similar to that of sperm-whale myoglobin. Finally, it may be noted that these surmises are not directly applicable to hæmoglobin, about the hæm positions in which differing conclusions have been drawn by different workers (see, for example, St. George and Pauling[2] and Keilin[3]); but they would be relevant if, as has more than once been suggested, the hæmoglobin molecule is made up of four sub-units each resembling that of myoglobin (in architecture, not amino-acid composition). In that case, there would be no necessary inconsistency even if the hæm groups of hæmoglobin were proved to be 'inside', since the arrangement of the sub-units (each having its hæm 'outside') might easily lead to such a configuration; equally, no difficulty would arise if the hæm groups of hæmoglobin were shown to be 'outside'.

Acetylation of Sulphanilamide in Plants

IN animals, sulphonamides are detoxified most commonly by acetylation of the free amino-group, a process usually localized in the liver[1]. In the course of a study of the movement of sulphanilamide in plants[2], it was found that part of the free drug became bound within the plant and that the change could be reversed by acid hydrolysis. The possibility that this change in the drug was due to acetylation has been investigated.

Broad bean plants (*Vicia faba* L.) were grown for thirty-three days with their roots immersed in an aqueous solution of sulphanilamide (100 μgm./ml.). The roots, stems and leaves of treated plants were sampled separately, killed in ether and the sap expressed[3]. 0.2-ml. aliquots of sap from treated plants were run on paper chromatograms (Whatman No. 1) in an *n*-butanol – acetic acid – water solvent system[4] (50–15–35 or 40–10–50) or an *n*-butanol – ammonia – water system[5] (40–10–50). In addition, sulphanilamide and acetyl sulphanilamide were added to the sap of untreated plants to give a final concentration of 50 μgm./ml. of the drug, and 0.2-ml. aliquots of these control solutions were run as markers. Chromatograms were run for 16 hr. at 25° C. and sulphanilamide spots were located by diazotization with a spray of 0.1 per cent sodium nitrite in glacial acetic acid and the addition of a coupling component, N-β-sulphatoethyl-*m*-toluidine[6] in 95 per cent butanol. The chromatograms showed the presence of sulphanilamide in the leaves of treated plants; but there was little free drug in the roots although bound drug could be revealed by hydrolysis. After the first diazotization and coupling, the papers were cut into sections 1 cm. × 2 cm. from the sulphanilamide spots to the solvent front, and each section was hydrolysed by boiling for 15 min. in 2 ml. *N* hydrochloric acid, the acid neutralized and the diazo colour produced. By measuring the optical density of the colour of these solutions in a spectrophotometer at 510 mμ, the position of acetyl sulphanilamide on the paper could be determined. Chromatograms of sap from treated plants showed spots with the same R_F value as acetyl sulphanilamide, indicating that acetylation of sulphanilamide occurs in plant tissue as in animal. There were greater concentrations of the acetyl compound in roots than in stems or leaves.

R_F values of sulphanilamide and acetyl sulphanilamide dissolved in various media were compared

Table 1 Comparison of R_F Values of Sulphanilamide and Acetyl Sulphanilamide in Various Media

Medium	Solvent system			
	Butanol – acetic acid – water		Butanol – ammonia – water	
	Sulphanil-amide	Acetyl sulph	Sulphanil-amide	Acetyl sulph
Water	0 64	0 80	0 59	0 79
Sap from treated plants	0 47	0 71	0 54	0 73
Sap from untreated plants with drug added	0 57	0 77	0 57	0 77

Differences of *p*H over the range 4 5–13 0 produced a change of only 0 01 in the R_F value , but the drugs in plant sap had lower R_F values than in water. This effect became more pronounced with longer exposure in plant sap, particularly with sap from treated plants (Table 1) The R_F value of sulphanilamide or acetyl sulphanilamide added to plant sap could be lowered to the same extent as that for the drug in sap from treated plants if an interval of 24 hr was allowed between adding the drug and running the chromatogram The butanol – ammonia – water system gave better separation and less tailing with the drugs in expressed sap than the butanol – acetic acid – water system

Acetylation in plants is being studied in further detail, but this preliminary note is published to direct attention to a process which may be a common phenomenon in plant tissues

Rat Liver Xanthine Oxidase in Carbon Tetrachloride Poisoning

During the course of experiments dealing with the effect of some hepatotoxic drugs on rat liver xanthine oxidase, it was found that this enzyme is activated when carbon tetrachloride is administered in a single necrogenic dosage The present communication presents results obtained in normal young rats injected subcutaneously with 0 1 ml /100 gm body-weight

Male Wistar white rats weighing 90–195 gm on a well-balanced diet were used throughout this study The animals were killed by decapitation 3–48 hr after the administration of the drug and food was withdrawn during the experimental period Normal controls showed that the injection of 0 1 ml /100 gm body-weight caused an acute congestion of the liver with a microscopic picture of focal necrosis characteristic of carbon tetrachloride injury, but no death occurred

Liver xanthine oxidase was determined by the method of Axelrod and Elvehjem from the oxygen uptake in a conventional Warburg manometer apparatus at 37° C , using xanthine as a substrate and air as the gas phase[1] The high endogenous respiration of liver homogenates does not permit the accurate assay of xanthine oxidase, particularly in cases where the activity of this enzyme is low The incubation of the homogenate at 37° C for 40 min before tipping the substrate partly suppressed the endogenous respiration. Recently, Dhungat and Sreenivasan[2] substituted a phosphate buffer of *p*H 7 4 for a pyrophosphate buffer of *p*H 8 6 in the determination of xanthine oxidase, based on the observation of Dixon and Elliott[3] that pyrophosphate inhibits endogenous respiration Therefore, this important improvement of the original method of Axelrod and Elvehjem was used in our experiments.

Table 1 Liver Xanthine Oxidase and Xanthine Dehydrogenase of Rats intoxicated with Carbon Tetrachloride and previously treated with Sodium Xanthine and Vitamin B_{12}

Vitamin B_{12} + carbon tetrachloride 24 hr †	2,460	1 9
Vitamin B_{12} + carbon tetrachloride 48 hr †	1,457	2 0

* Rats starved 24 hr , injected with carbon tetrachloride and killed 3 hr later

† Time of starvation after the administration of carbon tetrachloride

The xanthine dehydrogenase activity in rat liver was also measured using the anaerobic reduction of the colourless dye triphenyltetrazolium chloride in a Thunberg vacuum tube, and the red formazan extracted with toluol or with petroleum ether (ligroin) when the livers were rich in lipids[4]. The results for xanthine oxidase activity were expressed in c mm. of oxygen consumed in 60 min per gm dry-weight and for xanthine dehydrogenase activity in μgm. formazan per mgm dry weight.

Normal well-fed rats gave values for xanthine oxidase of 1,638 ± 168 c mm oxygen and rats starved for 24 hr and 48 hr values of 1,223 ± 32 c mm and 921 ± 177 c mm respectively Starved rats injected with carbon tetrachloride showed increased values which were statistically significant. When

† Vitamin B_{12} (15 μgm 24 hr before the administration of carbon tetrachloride)

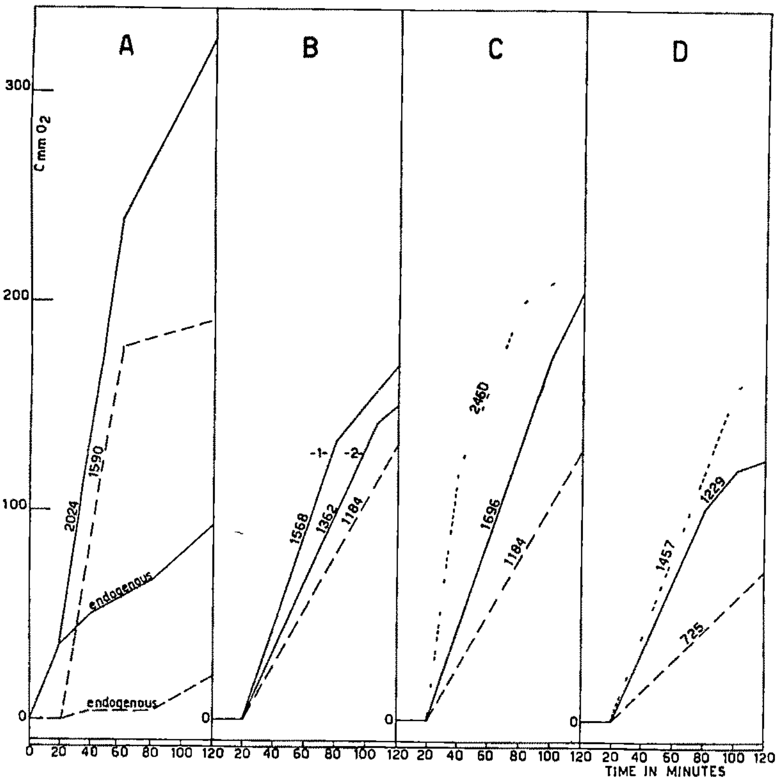

Fig 1 Activation of rat liver xanthine oxidase

(*A*) *in vitro* activation — — — —, normal , ————, same homogenate added with carbon tetrachloride (0 1 ml /10 ml)
(*B*) *in vitro* and *in vivo* activation — — — —, liver of normal rat starved for 24 hr , ——-1-——, *in vitro* addition of carbon tetrachloride , ——-2-——, xanthine oxidase rat starved 24 hr , injected with carbon tetrachloride and killed 3 hr later
(*C*) *in vivo* activation — — — —, normal rat starved 24 hr , ————, rat starved 24 hr and injected with carbon tetrachloride , , rat injected with vitamin B_{12}, and after 24 hr receiving carbon tetrachloride and then starved for 24 hr
(*D*) *in vivo* activation — — — —, normal rat starved 48 hr , ————, rat starved 48 hr and injected with carbon tetrachloride , , the same as in (*C*) but starved 48 hr

(Numbers on graph represent values of xanthine oxidase in c mm oxygen/gm dry-weight/60 min)

starved for 24 hr. and killed 3 hr after administration of carbon tetrachloride, increased values of xanthine oxidase were obtained ($t = 3\ 17$, $P < 2$ per cent), and for those killed after 24 hr and 48 hr. the values had still greater significance ($t = 5\ 9$, $P < 1$ per cent, and $t = 3\ 51$, $P < 1$ per cent)

Some typical results are shown in Fig 1 and Table 1 The *in vitro* addition of carbon tetrachloride (0 1 ml to 10 ml of the liver homogenate) activated the xanthine oxidase as shown in Fig 1, *A* and *B* It is interesting to note that the xanthine dehydrogenase activity decreased in the liver of the intoxicated rats (Table 1)

The activation of xanthine oxidase in rats treated with carbon tetrachloride was shown to be due to the oxidation of the substrate, as confirmed by simultaneous experiments in which the xanthine was measured colorimetrically after 120–180 min of the incubation of the whole system according to the method of Litwak *et al* [5]. These results are summarized in Table 2. The livers of the rats injected with carbon tetrachloride and killed after 48 hr. showed a smaller increase of activity than those killed after 24 hr , a fact possibly related to the regeneration of the liver during this time

It is known that sodium xanthine and liver extracts containing xanthine are able to protect the rat liver against the necrosis occurring in carbon tetrachloride poisoning[6] Experiments were carried out to find the effect of sodium xanthine in normal rats and rats treated with carbon tetrachloride as well as of vitamin B_{12} (cobalamin), which was claimed by Popper *et al* [7] to prevent liver necrosis Sodium xanthine (100 mgm /100 gm body-weight) had no effect on liver xanthine oxidase in normal rats, but inhibited its enzyme activity of about 50 per cent in rats injected with carbon tetrachloride However, xanthine dehydrogenase decreased in normal as in poisoned rats (Table 1) Vitamin B_{12}, kindly supplied by Merck and Co , Rahway, N J , injected at 15 μgm /100 gm. body-weight, was without effect on the xanthine oxidase and dehydrogenase activities of normal rats , but both these activities were much increased in rats treated with carbon tetrachloride (Table 1 and Fig 1, *C* and *D*)

The results reported here indicate that liver xanthine oxidase is activated and xanthine dehydrogenase partly inhibited by carbon tetrachloride when injected in a single dose Sodium xanthine, which protects the rat against liver injury in carbon tetrachloride poisoning, inhibits the oxidase and dehydrogenase activities of this enzyme in intoxicated animals However, vitamin B_{12} increases these activities notwithstanding its protective effect in this experimental intoxication.

Infectivity and Nucleic Acid Content of Influenza Virus

Much of the present belief that the genetic properties of viruses are carried by their nucleic acid moieties arises from recent work with plant and bacterial viruses Infection of the host cell has been shown to result in the formation of particles which, though closely related to the accompanying virus components, are non-infectious Analyses indicate that the non-infectious material contains little or none of the nucleic acid present in the infectious particle[1]

Methods have been described for producing influenza virus preparations which differ from 'standard' virus in possessing high hæmagglutinating activity but low infectivity[2] Such preparations have been termed 'incomplete', the degree of incompleteness being indicated by the ratio of infectivity to hæmagglutinin, *I*/*A* It seemed worth while to see if any correlation existed between the degree of incompleteness and the nucleic acid content of the virus particle The preliminary results of such an investigation are reported here.

All experiments were carried out with the *PR*8 strains of influenza virus Infected allantoic fluids, harvested 30–42 hr after inoculation with virus diluted to $ID_{50} = 10^{-4}$, served as a source of standard virus, whereas incomplete virus was prepared from infected allantoic fluid harvested after two or three serial passages (each 12–16 hr) of undiluted (initially $ID_{50} = 10^{-9}$) inoculum[2,3] Hæmagglutinin and infectivity titres[4] were determined on the freshly harvested fluids. The virus was purified by adsorption on to, and elution from, human red cells followed by two cycles of differential centrifugation (45,000 *g*, 30 min , 6,000 *g*, 10 min) Yields of purified virus varied from 20 to 60 per cent The virus was precipitated with trichloracetic acid, dialysed against distilled water and dried from the frozen state *in vacuo* The degree of purity was estimated by comparing the ratio hæmagglutinin units/mgm. dry-weight Values given by standard and incomplete virus preparations fell within the same range, 6–12 × 10^4

It has recently been found that influenza virus contains only ribonucleic acid in significant amounts, no appreciable amount of deoxyribonucleic acid being present The ribonucleic acid content could be conveniently estimated by measuring the ultra-violet absorption at 260 mμ of a hot 10 per cent sodium chloride extract of defatted virus. Values of approximately 0 8 per cent for standard virus preparations were obtained[4].

In Fig 1 are plotted nucleic acid values of purified virus prepared from infected allantoic fluids the *I*/*A* ratios of which varied from $10^{6\ 5}$ to $10^{3\cdot 2}$ There is a considerable spread in these ratios for the different experimental groups, due largely to seasonal variations in the eggs. Also, virus preparations having similar *I*/*A* values show an appreciable range of ribonucleic acid values, and this appears to be partly due to varying lipid content. Despite these variations, it is clear that reduction in the *I*/*A* ratio is accompanied by a progressive decrease in the nucleic acid content, the latter being expressed as the percentage per mgm. dry-weight of virus As originally reported[2], however, incomplete virus has a lower sedimentation constant than standard virus, and recent work[5] indicates that this may be due to the high lipid content (and hence lower density) of the former Thus, expressing the above values on a weight of ribonucleic acid per virus particle basis would increase the difference between the ribonucleic acid content of standard and incomplete virus. The magnitude of the change must await the results of virus particle counts

It was thought possible that some indication of the specificity of the missing components in incomplete virus could be obtained by comparing the gross proportion of bases in preparations of different *I*/*A* ratios. When analysed by chromatography following hydrolysis with *N* hydrochloric acid[6], the nucleic acid isolated from the sodium chloride extract gave spots coinciding in R_F values with adenine, guanine, cytidylic acid and uridylic acid obtained from yeast nucleic acid Six preparations with *I*/*A* values ranging from $10^{6\cdot 5}$ to $10^{4\ 3}$ gave identical proportions of base

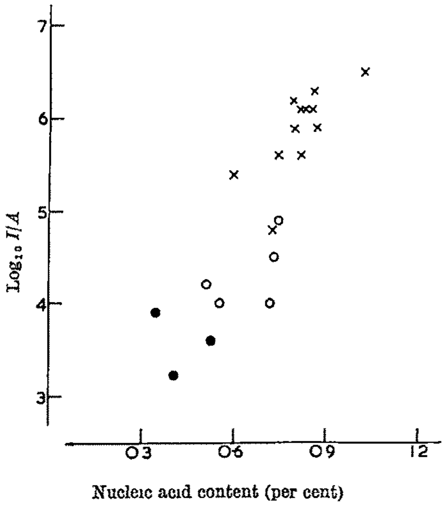

Fig 1 Relationship between the infectivity/hæmagglutinin ratio and the nucleic acid content of influenza virus ×, Single passage (0 05 ml , $ID_{50} = 10^{-4}$) , ○, double passage (each 1 0 ml undiluted fluid) , ●, triple passage (each 1 0 ml undiluted fluid)

It seems not unreasonable to postulate that loss of infectivity is caused by the lack of a small proportion only of genetic units corresponding to the observed decrease in nucleic acid content Sufficient nucleic acid is present in particles which are 99 per cent incomplete to suggest that they still contain genetic material which could contribute to the 'genetic pool' in recombination experiments, and such has been found to be the case[7] However, the present limited evidence does not indicate whether the decrease in infectivity is due to a random or orderly loss of genetic units

Total Sugar and Nitrogen Contents of Jute Plants, with Special Reference to the Flowering Stage

The relative increase of carbohydrate over nitrogen has been regarded as a sign of a shift from the vegetative to the reproductive state in plants The ratio of soluble sugar and nitrogen in normal and in photoperiodically induced plants was determined in jute, which has been found to be a short-day plant[1] Total sugar and total nitrogen calculated as percent-

Table 1 *Corchorus capsularis* AND *C olitorius* SOWN ON APRIL 20, 1954

C capsularis					*C olitorius*				
Treatment	Sampling date in days after sowing	% Sugar (*A*)	% Nitrogen (*B*)	*A*/*B*	Treatment	Sampling date in days after sowing	% Sugar (*A*)	% Nitrogen (*B*)	*A*/*B*
10 hr (in flower)	29	0 879	1 939	0 04533	10 hr (in flower)	21	0 4155	2 215	0 1875
Control (vegetative)	29	0 0245	5 0225	0 004877	Control (vegetative)	21	0 2205	2 044	0 1079
					,, (in flower)	117	0 391	2 044	0 1914

age of dry-weight of the whole plant are given in the tables as a mean of four plants

The sugar–nitrogen ratio is comparatively higher in the plants which are induced to flower early The work of Parker and Borthwick[2] and Murneek[3] on soybeans gives similar results

The sugar and nitrogen contents of plants before, at, and after flowering were determined at intervals of five days in *C olitorius* sown on March 15 It is known[4] that this species when sown in March flowers very early under natural conditions The results are given in Table 2

Table 2 *C olitorius* SOWN ON MARCH 15, 1954

Date of sampling	% Sugar	% Nitrogen	Sugar/nitrogen
26 3 54	11 046	3 65	3 026
31 3 54	2 5	4 2203	0 5978
5 4 54 (Flowering)	0 2763	0 7781	0 355
10 4 54	4 6135	6 244	0 7393
15 4 54	1 614	1 203	1 342

Both the sugar and nitrogen contents are found to fall considerably at the flowering stage, but rise again after the date of first initiation of flowers

Analyses of plants sown in the normal season and induced photoperiodically to flower early, at regular intervals before and after flowering, will be of interest For a more complete knowledge of the relationship, determinations of total carbohydrates including starch will be necessary.

Cortical Zonation and Survival of Chromaffin Cells in Adrenal Autografts

IN the earlier investigations relating to the transplantation of the adrenal gland, which were summarized by Biedl[1], success depended largely upon the preservation of the original blood supply of the gland, and in consequence the organ had to remain in close proximity to its original bed The later work of Ingle and Higgins[2] showed that, when the gland is transferred to distant sites, all except a few cells of the glomerulosa degenerate and that these surviving cells then proliferate and produce a mass of cortical tissue Greep and Deane[3] have shown that the subcapsular cells of the enucleated rat adrenal gland are capable of reforming a complete gland (less medulla) in which the three descriptive zones—glomerulosa, fasciculata and reticularis—can be recognized.

In the present work, a series of twenty adult rabbits and six adult rats have been subjected to a left adrenalectomy The gland is then divided into two parts by a cut at right angles to its long axis and a slice 0 5–1 mm. in thickness removed from the cut face with a razor-blade The medulla and cortex can be readily distinguished in such a slice by the translucency of the former and white opacity of the latter The medulla and cortex are separated as accurately as possible along the cortico-medullary junction, washed in isotonic saline and the medullary portion inserted into the anterior chamber of the left eye

In the rabbit, during the first two weeks, degenerative changes affect some phæochromocytes and some cortical cells—the latter are invariably present as the zona reticularis extends as a series of cords into the medulla and may reach the central vein An occasional mitotic figure is observed in the cortical cells but not in the phæochromocytes The graft is firmly attached to the iris after two weeks and vascularization is well marked by one month In grafts aged two months and older, the cortical cells are more numerous than those of the medulla, and in two aged three and four months a typical peripheral glomerulosa (Fig 1) has been observed which adjoins anastomosing cords of cortical cells, groups of phæochromocytes are scattered throughout the cortical tissue and give a strongly positive chromaffin reaction Both cortex and medulla have been found in all specimens so far examined

To date few rats have been killed for examination, but in those few both cortex and medulla exist in the grafts

The source of the cortical cells is of importance. In taking the grafts, the knife blade was so far as possible kept on the cortico-medullary boundary, and hence the cells are mainly, if not entirely, derived

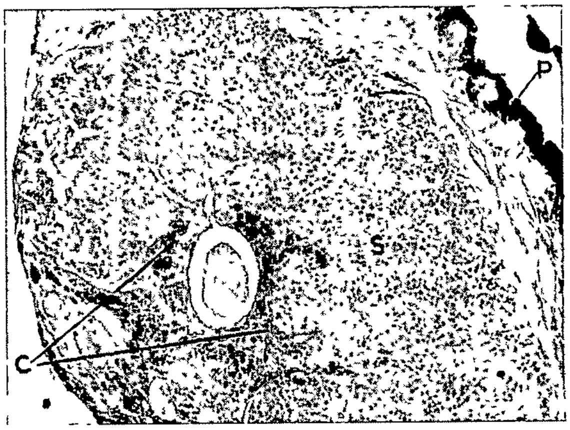

Fig 1 Section through a four-month old graft of rabbit adrenal medulla and associated cortical cells *P*, pigmented layer of iris; *C*, chromaffin cells, *S*, cortical cells

from the zona reticularis , although it is impossible to rule out entirely the presence of an occasional cell from the inner part of the fasciculata, these must at the most be few in number The technique used and method of introduction into the eye precludes the possibility of transferring detached cells of the outer fasciculata or glomerulosa

The proliferation of these inner-zone cortical cells is in keeping with the views of Blackman[4], Yoffey[5] and others, who regard the zona reticularis as a functionally active zone, while the formation of a peripheral glomerulosa in the absence of subcapsular cells supports the views of Jones and Wright[6], who consider that mechanical factors are responsible for the existence of this zone in the Eutherian adrenal cortex • Cortical cells in the graft multiply (as evidenced by mitotic figures), even when the right adrenal is intact , mitotic figures have not, however, been observed in chromaffin cells, and it appears that, although these elements persist, regeneration does not occur

A Substance from Eel Serum producing Slow Contractions

EEL serum is well known for its hæmolytic and toxic properties[1] , but so far no report seems to have been published dealing with its effect on isolated organs In the course of investigations into the effects and components of various animal venoms, it was noted that eel serum contained a substance which causes a delayed, slow contraction of the isolated guinea pig ileum and bears some resemblance to the substances producing slow contractions present in wasp venom[2] or appearing in cat plasma after intravenous injection of thalassine[3]

The material possessing this property proved so potent that in most cases it was found impossible to test its effect by applying undiluted serum to a sensitive preparation like the isolated guinea pig ileum suspended in magnesium-free Tyrode solution When eel serum was diluted with 0 75 per cent saline to make a final dilution of 1 10 to 1 50, doses corresponding to as little as 0 002–0 01 ml of the original serum contracted the gut suspended in an organ-bath of 18 ml capacity The contraction began after a typical latency of 10–45 sec and reached its maximum after 60–90 sec It persisted following treatment of the gut with atropine and neoantergane in doses sufficient to suppress strong acetylcholine or histamine contractions, and also remained unaffected after tryptamine desensitization[4] In contrast to the substance present in wasp venom causing slow contraction, repeated doses of eel serum were progressively less active even if the interval between the contractions was extended to 15 min and more , the gut then still responded to histamine in the usual manner.

If eel serum diluted with 0 75 per cent saline was dialysed against distilled water for up to 72 hr , no appreciable activity could be detected in the dialysate, whereas practically all of it could be recovered in the inner compartment, thus indicating that the active component is most probably a large molecule The material producing the slow contraction was little affected by boiling diluted serum at neutral *p*H for 5 min but was destroyed after a few minutes of this procedure in 0 1 *N* sodium hydroxide

Undiluted eel serum caused a contraction of the isolated rat colon resembling that produced by serotonin in very small amounts If all the activity detected by using the rat colon as a test organ is taken as representing serotonin, eel serum would contain about 0 03 µgm serotonin per ml , a figure which is in good agreement with that published by Erspamer and Faustini[5] for extracted eel serum No evidence for histamine occurring in appreciable amounts in eel serum was obtained Small doses of eel serum produced vasoconstriction of long duration in the isolated rabbit ear perfused with Ringer–Locke solution at room temperature

The nature of the material producing slow contraction is being further investigated and a detailed account of this work will be published elsewhere

Spontaneous Microscopic Activity in Cardiac Muscle

WHEN the heart stops beating, pulsations in individual cardiac muscle fibres continue This can be observed by examining thin sections of living cardiac muscle under high-power magnification and transmitted light The pulsations appear to be due to alternate relaxations and contractions of the fibres, with a concomitant change in the width of the striations Under low-power magnification and by reflected light, the activity seen in the isolated mammalian heart is that of spontaneous minute contraction waves Prinzmetal *et al* [1] have noticed a similar though much faster activity in human and dog fibrillating auricles It disappeared with the cessation of fibrillation

These spontaneous minute contraction waves can be observed not only in non-beating hearts but also when the latter beat slowly *in situ* This fact makes it uncertain if the pulsatile activity seen under high-power magnification and the spontaneous minute waves are one and the same phenomenon, and whether the pulsations are present only after cessation of the co-ordinated beat or whether they are a normal accompaniment of the heart-beat

The spontaneous minute waves have been seen in all mammalian hearts so far examined, and their survival-times have been found to vary considerably, the longest seen so far being in rabbit auricles (stored at 4° C) in which they could still be observed six days after isolation

A study of the response of the spontaneous minute waves to changes in environment has shown that they are insensitive to relatively wide fluctuations of temperature.

The appearance of these waves to the eye is much like that of fibrillation in skeletal muscles; but the length of survival and the insensitivity to temperature fluctuations distinguish them from that phenomenon. It may be, however, that the phenomenon is essentially the same in both cases, but that its different characteristics in skeletal and cardiac muscle reflect rather intrinsic differences in these two types of striated muscle. It may be noted that Langley[2] found in cats that fibrillation may last half an hour after the death of the animal and thought this to be remarkably long.

Langley also noted that fibrillation in skeletal muscle is very sensitive to fluctuations of the normal temperature, cessation of fibrillatory activity being very quickly brought about by a fall from body to room temperature. Furthermore, if the spontaneous minute waves are due to fibrillation of the cardiac musculature, it is difficult to conceive how it is that they can be seen in the slowly beating heart, in which no apparent sign of fibrillation can be detected. On the other hand, like fibrillation, the spontaneous minute waves have been found to be sensitive to quinidine and procaine, both of which cause arrest of their activity. Urethane[3] was not found to prolong or increase their activity when drying of the surface film was prevented throughout the period of observation.

The following observations indicate that the spontaneous minute waves are present throughout the myocardium. When the heart is cut into small fragments, they continue their activity uninterruptedly. They are present in both ventricles and atria, and they can be observed on the walls of the chambers of the heart as well as on the outer surface. They are coarser and much more vigorous on the inner surfaces.

It is hoped to publish fuller details of this work elsewhere.

Phenolic Substances of Pear–Apple Hybrids

THE leaf of the apple contains as its principal phenolic the glucoside phloridzin. This is present in all *Malus* species examined, together with smaller amounts of the corresponding aglycone phloretin, a quercetin glycoside[1], and traces only of chlorogenic acid and *epi*catechin. Pear leaf, in contrast, contains three phenolics in quantity: chlorogenic and *iso*chlorogenic acids[2] and the glucoside arbutin, with small amounts of catechin, *epi*catechin, flavonol glycosides and hydroquinone, the aglycone of arbutin.

The glucosides phloridzin and arbutin appear to be quite specific in their distribution; in the course of a wide survey of leaves of apple and pear species and varieties by paper chromatography, phloridzin has been found in all apples, but never in pears; conversely, arbutin has been found in all pears but not in apples.

The production of true sexual hybrids between the pear and apple[3] raised the question of the possible dominance of part or all of one phenolic pattern in the hybrid leaf. Through the kindness of the Director of the John Innes Horticultural Institution, it has been possible to examine leaves from a number of different pear–apple hybrids. Because of the limited amount of material available, 70 per cent alcoholic extracts of two-leaf samples were examined by paper chromatography in three different solvent systems; this enabled all the major and some, though not all, of the minor phenolics to be identified.

In all samples, the results indicated addition of the individual phenolic patterns in the hybrids; the leaves contained phloridzin, arbutin, chlorogenic and *iso*chlorogenic acids in quantity, with lesser amounts of phloretin, *epi*catechin and flavonol glycosides. The amounts of each phenolic present varied somewhat among the different hybrids, but in no case were any of the typical phenolics completely absent. In the two triploid hybrids (diploid pear × tetraploid apple), the pear phenolics were relatively weaker than in those hybrids in which both parents were diploid or tetraploid.

This apparently simple addition of the parental phenolic patterns in the hybrids contrasts with the dominant-recessive relationships found with the anthocyanin colouring matters of flowers in intraspecific crosses.

Growth of *Chondromyces crocatus* in Pure Culture

THE genus *Chondromyces* was named and illustrated, but not described, by Berkeley and Curtis in 1857 in Berkeley's[1] "Introduction to Cryptogamic Botany". It was apparently next seen by Thaxter[2], who reported that he grew it in pure culture. In 1913, this species was stated by Pinoy[3] to grow only in the presence of *Micrococcus*. Beebe[4] reported the presence of *C. crocatus*, but attempts to purify the organism failed completely though it grew readily with various bacteria in mixed culture. Kuhlwein[5] stated that *C. crocatus* could not be grown in pure culture and that it was a symbiotic form. Oetker[6], recently, has shown that several species in the genera *Myxococcus* and *Podangium* can grow upon yeast and algae.

C. crocatus, which may represent the highest morphological and nutritional specialization in the entire order Myxobacteriales, has recently been isolated from soil in our laboratory. The soil sample, obtained in Iowa, consisted of surface debris and soil taken from a permanent bed of rhubarb which, for a number of years, had been heavily fertilized with chicken manure. The organism was found growing on hay agar plates inoculated with a heavy suspension of soil. It grew very slowly and was not observed for almost six weeks after the streak inoculation had been made. Cysts were removed from the cystophores and inoculated at the centre of crossed streaks of *Escherichia coli*, *NRRL B*-281, on hay agar. Growth of the *Chondromyces* proceeded in all directions from the point of inoculation. Repeated re-isolations from the advancing edge of growth yielded a 'pure-mixed' culture of *E. coli* and *C. crocatus*. This technique[7] was recommended by Raper for the purification of new isolates of members of the Acrasiales. In these mixed cultures, vegetative development was particularly good along the streaks of living *E. coli* cells. Between the radiating bands of *E. coli*, where the *Chondromyces* was free of the host cells, growth also occurred. When *Chondromyces* cells from these areas were inoculated on a variety of media, no growth could be obtained. In pure-mixed cultures, abnormal fruiting with very limited cyst formation was found to occur only at the edge of the dish. The presence of chance mould contaminants seemed to promote normal cyst formation.

Interest in the mechanism of lysis of the host cells led us to employ a yeast in which the larger cell-size would facilitate microscopic observations. Hence hay agar plates were inoculated in the above fashion with a culture of *NRRL Y*-1656, *Hansenula anomala*. When these were inoculated with cells free of *E. coli*, as described above, growth occurred which was as good as, or better than, with *E. coli* cells. This is the first report to our knowledge of the growth and lysis of yeast cells by any member of this genus, although Oetker[6] recently reported growth on yeast in two other genera of the Myxobacteriales.

Subsequent studies to be published elsewhere on the nutrition of this organism have shown *C. crocatus* can grow not only on live yeast cells but also may be kept in pure culture on autoclaved cells of yeast. It has been carried through many transfers in pure culture in this manner at 24° C. Growth, although not as good, also occurs on the filtrate from yeast cultures from which all yeast cells are removed. Yeast extract, however, has not supported growth. Solidified vitamin B_{12} assay medium with vitamin B_{12} added also failed to support growth. The factor for growth of *Chondromyces* has been found to be present in liver extract and in large quantities in bovine serum. Purity of the culture of *Chondromyces* was determined by inoculating deep liver broth and various other nutrient media as well as direct microscopic examination. Accepting Thaxter's report of the cultivation of this organism in pure culture as accurate, this communication appears to represent the second report of the growth of *C. crocatus* free of all other living organisms.

Shape of Bacterial Flagella

IN orthodox bacteriology all flagella are curly. With the exception, however, of spirilla, which possess unchanging horny-looking curly appendages (Fig. 1) directly derived from the cell wall[1], motile bacteria usually go forward with a fuzzy-looking straight tail (Fig. 2) and a twisting body[2]. Under various, probably adverse, conditions this straight tail tends to stiffen into a straight clear-cut rod but more often into a clear-cut helix[3]. The straight tail of Fig. 3 actually became the helix of Fig. 4, and the helix of Fig. 5 also arose from a straight tail. The helices may show two different but characteristic wave-lengths in the same bacterium, one always exactly twice the other as in Figs. 4 and 5, for which phenomenon 'biplicity' would appear a suitable term[3].

The transition from straight tail to helix initially is reversible, but after no matter how many reversals the final shape always is the helix. Normal swimming usually continues during these changes, but after them tends to come to a gradual stop, with the bodies becoming rigid. Often the helices then start whirling movements lasting several minutes. These may push a rigid bacterial body about in erratic fashion, or, if the body has stuck, create maelstroms. This anomalous movement has been mistaken for normal motility and as proof that helices are motor-organs. 'Flagella staining' habitually undertaken at this stage naturally shows curly flagella, and in the disfigured dried material 'biplicity' gets lost.

Figs. 3 and 4 illustrate the recent observation that the transition from straight tail to helix is not accompanied by a change in overall length (measured from free tip to body).

Calculation shows that when a straight tail of 10·75 µ overall length changes into a helix of identical overall length, with five windings of a wave-length of 2·15 µ, and an amplitude of c. 0·35 µ, the real length of the structure becomes c. 12·05 µ, which is an increase of c. 12 per cent. A straight tail of 4·9 µ overall length becoming a helix of five windings of the rather short wave-length of 0·98 µ and an amplitude of c. 0·35 µ changes its real length from 4·9 µ to c. 7·35 µ, an increase of c. 50 per cent. These are values from actual measurements.

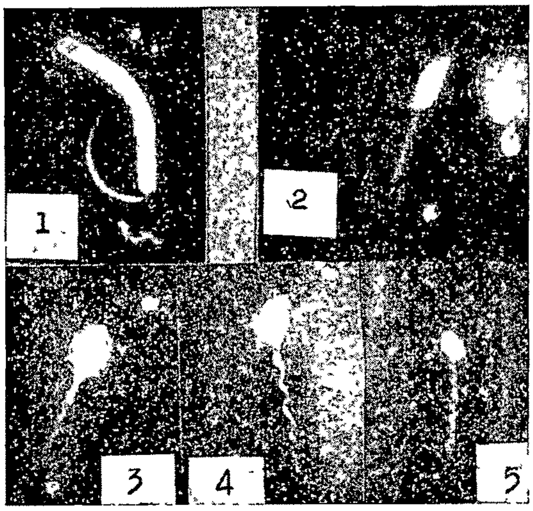

Fig. 1. *Spirillum volutans*. × 1,000
Fig. 2. *Salmonella typhi*. × 1,500
Figs. 3–5. *Salmonella paratyphi B*. × 1,500

How is this helical lengthening brought about? Electron photographs are usually taken at the helical stage and show disorderly masses of submicroscopic wavy fibrils lying around and across bacterial bodies, no straight tail has yet been electron-photographed in the electron microscope.

The transition from straight tail to lengthened helix would seem to necessitate molecular transformations Such helical rearrangements in the tail might well create tensions or liberate forces capable of setting up the anomalous transient whirling movements described above

The helix in some bacteria can be seen to split suddenly into a number of thinner similar helices, these may stay terminal, or float about and become distributed over the surface of their own or other bacterial bodies In this way the so-called monotrichous, lophotrichous and peritrichous types of flagellation are seen to arise Their common origin is the straight tail, the structure primarily associated with normal motility and which therefore seems entitled to some of the attention so far bestowed on its more elegant curly derivatives

These observations were all made with the sunlight dark-ground microscopy described previously[2]

Use of Snail Stomach Cytase in Plant Cytology

DURING a study of the large New Zealand fern genus *Blechnum*, it was found virtually impossible to obtain somatic chromosome counts by orthodox methods This aspect of the problem was about to be abandoned when a paper by Fabergé[1] on the use of snail stomach cytase for maceration in cytology was discovered There appears to be a general lack of knowledge of this method and its advantages Manton[2], for example, makes no mention of it.

Well over a thousand root-tip preparations were made by aceto-carmine squash methods with various modifications, but no really satisfactory results were obtained Fabergé's technique with certain refinements gave outstanding results, almost every preparation yielding good counts (see Fig. 1) Previously adequate spreading had been impossible The method has been applied to other groups of plants and is showing considerable promise

Fabergé mentions the possible use of species of snail other than the edible *Helix pomatia* which he utilized. In New Zealand the only snail available in sufficient quantity is the considerably smaller but cosmopolitan species *Helix aspersa* Mueller With large snails the crop and stomach contents only are used with small specimens, however, these whole organs are removed and pulverized in a little water To the extract from about two dozen snails, about 15 ml of distilled water is added This is followed by centrifuging at 4,000 r p m. for 5 min The clear brown supernatant liquid is then ready for use A sample of enzyme if stored in a refrigerator remains effective for at least three batches of root tips Between uses, any stray cellular material from tissue previously treated must first be removed by centrifuging Preliminary tests have shown that the activity of the enzyme complex has a wide temperature-range The root-tip material is prefixed in a saturated aqueous solution of *p*-dichlorobenzene and then fixed in alcohol – acetic acid (3 1 mixture). Before being placed in the enzyme the root-tips are given two changes of a few minutes each in water Blotting between changes is essential Over-night treatment in cytase at room temperature is satisfactory (or 3–4 hr at 25° C is sufficient) A longer period in cytase tends to make staining more difficult, and the outlines of the chromosomes become diffuse Lengthy treatment may be useful in studies on coiling, as the coils become more apparent. A rinse in tap-water followed by at least a minute in 45 per cent acetic acid assists the aceto-carmine staining

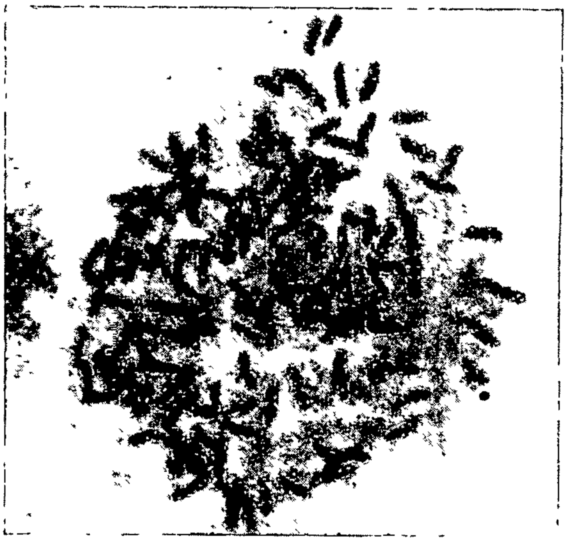

Fig 1 Root tip preparation from a tetraploid race of *Blechnum fluviatile*, somatic number = 132

It is believed that this method has advantages which deserve wider recognition among cytologists

Selective Fertilization following the Use of Sperm Mixtures in the Mouse

ARTIFICIAL insemination has been carried out in the mouse using mixtures of sperm from a number of inbred lines each containing a suitable genetic marker The lines are *REB* (containing the dominant hair structure gene rex, *ReRe*), *G* (coat colour and pattern tan, a^ta^t), and C_3H (coat colour agouti, *AA*), all possible combinations of these genes are phenotypically distinct in the offspring The first two lines are derived from inbred lines *A* and *CBA* respectively Sperm is obtained from the vas deferens of killed males and the density of each sample estimated by hæmocytometer counts Sperm mixtures were made with equal numbers of spermatozoa from each donor, the donor males for each mixture were of approximately the same age Four types of sperm mixture

were made, namely, a triple mixture of all three types and three double mixtures containing the three possible pairs of the types These mixtures were used for inseminating œstrous females of the same three lines Since fertility was rather low in the inbred lines[1], the same sperm mixtures have also been used on other females taken from highly fertile non-inbred strains These are referred to as *X* in the tables, which give the results obtained up to the present time

Certain facts are noteworthy in these results First, the mixture of *REB* and C_3H sperm produced a significant excess of eggs fertilized by C_3H sperm This is not due to the death and resorption of the homozygous *REB* animals, because the same result occurs where C_3H are the homozygotes, and also in the non-inbred females The result has been rather consistent throughout the series of nine such sperm mixtures which have been employed (Table 2) Secondly, in the other two double sperm mixtures there is less evidence of unequal efficiency of, or interaction between, sperm types, though the mixture C_3H and *G*, and the small series from the triple mixture, again suggest that C_3H is slightly more effective From the triple mixture one tri-paternal litter has been produced[2], an *REB* female having given birth to a litter of five, three derived from the C_3H sperm and one each from *G* and *REB* sperm

These results clearly show that in sperm mixtures the chance of fertilization by a particular type may not be the same for all components of the mixture At the present stage in the work, several different interpretations of this fact are possible It may be that the C_3H sperm is always more efficient than that of the other two lines involved It may be, however, that the C_3H sperm exerts a specifically depressant effect on *REB* sperm The experiment is so designed that it should be possible to decide between these two possibilities as more numbers accumulate One should, further, be able to discover whether there is any tendency for a reaction of one sperm type either with one particular egg type, or with a particular uterine environment, a possibility which should be borne in mind, though there is as yet little sign of it

This work has been supervised by Dr R A Beatty. I wish to thank Prof C H. Waddington for his interest, and the University of Edinburgh for a postgraduate studentship

Role of the Nuclei of the Follicle Cells in the Formation of the Chorion in *Cimex lectularius columbarius* Jen.

The follicular epithelium in insects is said to secrete the chorion after the egg is fully formed According to Snodgrass[1], the follicular epithelium secretes a substance which is discharged over the fully formed egg and there hardens to form the chorion Wigglesworth[2] is also of similar opinion. The subject has also been touched upon by Biedermann[3], Cappe de Baillon[4] and Beament[5].

In the course of work on the female reproductive system of the bug *Cimex lectularius columbarius* Jen, collected from the fowl-house of the Indian Veterinary Research Institute, Mukteswar-kumaon, U.P, India, we have found cases in which chorion appeared to be laid down not as an ordinary secretory product of the follicular epithelium, but as something of deeper significance, in which methyl green - staining materials present in the nuclei of the follicular cells were involved.

Ovarioles fixed in Carnoy's fluid and stained with Unna–Pappenheim stain (Fig 1) revealed that the chorion when it was being laid down consisted of three layers an inner layer which took up faint pyronine stain, a middle layer which took up methyl green stain , and an outer layer which showed very faint affinity for pyronine The outer layer sent small spine-like processes outwards, the pointed ends of which were found to be inserted in the nuclei of the follicular cells Globules deeply stained with methyl green were found migrating from the nuclei

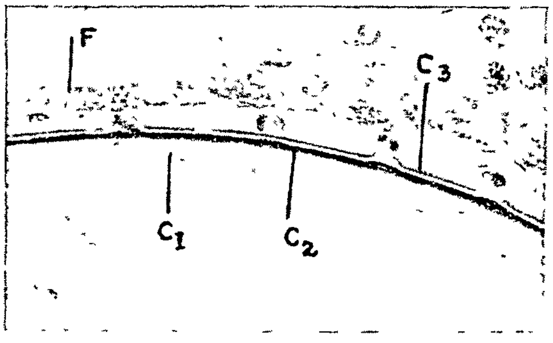

Fig 1 Microphotograph of a part of a section passing through the ovariole of *Cimex lectularius columbarius* Jen, fixed in Carnoy's fluid and stained with Unna–Pappenheim stain × 350 *F*, layer of follicular epithelium C_1, C_2 and C_3, inner, middle and outer layers of chorion respectively Note the globules stained by methyl green in the spine-like processes of the outer layer (C_3)

of the follicular cells through these spine-like processes into the substance of the developing chorion The formation of the chorion in this insect was thus found to be due to the direct intervention of the nuclei of the follicle cells, and in this vital process material staining with methyl green (deoxyribonucleic acid) present in the nuclei of the follicle cells assumed the major role

It is suggested that the whole process of the laying down of the chorion due to nuclear activity is one of short duration, and hence the fixation of the material at the right moment for studying this phenomenon is largely a matter of chance

The spine-like processes through which the material staining with methyl green travels persist on the outer surface of the fully formed chorion It may be noted here that these processes were noticed by Cragg[6] in *Cimex lectularius* and in *Cimex rotundatus* He thought that they served to anchor the egg in position when it was laid

We gratefully acknowledge the award of a research fellowship by the Indian Council of Agricultural Research to one of us (B D)

Added in proof Fresh material has been subjected to the Feulgen technique It was found that the middle layer of the chorion which took up methyl-green stain also gave a strongly positive reaction for deoxyribonucleic acid with this technique The methyl green - staining globules mentioned above were found to be Feulgen positive.

Rearing Experiments on Marine Teleost Larvæ and Evidence of their Need for Sleep

During a study of the biology of the shore fishes *Blennius pholis* L and *Centronotus gunnellus* (L) several series of experiments have been carried out on the rearing of the larvæ By keeping sufficient eggs in the aquaria it was possible to obtain large numbers of larvæ of similar age These were evenly distributed between bell-jars which each contained 25 litres of sea water and about fifty larvæ It was soon found that mechanical stirring by plunger plates as used by previous workers[1] was accompanied by very heavy mortality of the larvæ The water was therefore kept circulating slowly by gentle streams of small air bubbles The different batches of larvæ were subjected to various conditions of food and illumination Larvæ which died were removed daily and percentage survival was used as criterion for comparison between batches Surviving larvæ grew well, and given suitable conditions a small percentage of these species and of *Cottus scorpius* L were reared until metamorphosis, when they adopted the demersal habit of the adults

It seemed desirable to investigate the nutritional value of phytoplankton cultures, which if suitable would give an easy solution to the problem of providing food Green plant remains have frequently been observed in the stomachs of larval fishes freshly caught from the plankton[2]. Though it has recently been discovered that green pellets found in plaice larvæ from the southern North Sea were fæces of ingested *Oikopleura*[3], it was clearly shown by Gross[4] that herring larvæ kept in the laboratory with cultures of *Chlamydomonas* would fill their guts with green flagellates This was confirmed with larvæ of *B pholis*, *C gunnellus*, *C scorpius* and *Nerophis lumbriciformis* (Pennant)

On examination under a low-power binocular microscope, the young fishes were seen to show a rhythmic peristalsis, which started at the posterior end of the pharynx and travelled posteriorly down the whole length of the narrow œsophagus This swallowing movement was most easily seen in *Centronotus* larvæ, because of their straight gut and slight pigmentation Particles suspended in the sea water were taken in slowly through the open mouth, became arranged in a linear fashion in the narrow œsophagus, and then were forced posteriorly by the peristaltic movements No strong current into the mouth was observed when the fishes were under observation in small dishes , but it seems likely that water is taken in more readily during the course of swimming, for larvæ kept in rearing jars usually had their guts visibly coloured by algal cells, although these were supplied in only moderate concentration

Nevertheless, the large quantities of flagellates and diatoms ingested did not have a markedly beneficial effect upon survival of these larvæ Cultures of *Chromulina pusilla* Butcher, *Isochrysis galbana* Parke, *Chlamydomonas* sp , *Chlorella stigmata* Butcher, and *Prorocentrum micans* Ehrenberg were tried separately in the laboratory with larvæ of *Centronotus*, but the resulting survival-rate was at most only slightly greater than in the larvæ kept without food Similar results were obtained with *B pholis* (Fig 1, *A* and *B*). When these flagellates and diatoms were offered together with nauplii of barnacles and *Artemia*, survival was not significantly better than in larvæ fed on nauplii alone Experiments on these lines are still in progress and it may be possible eventually to demonstrate that phytoplankton organisms have some slight value as food, but it is clearly impossible to rear the larvæ on such organisms alone The ingestion of such organisms is probably connected with the

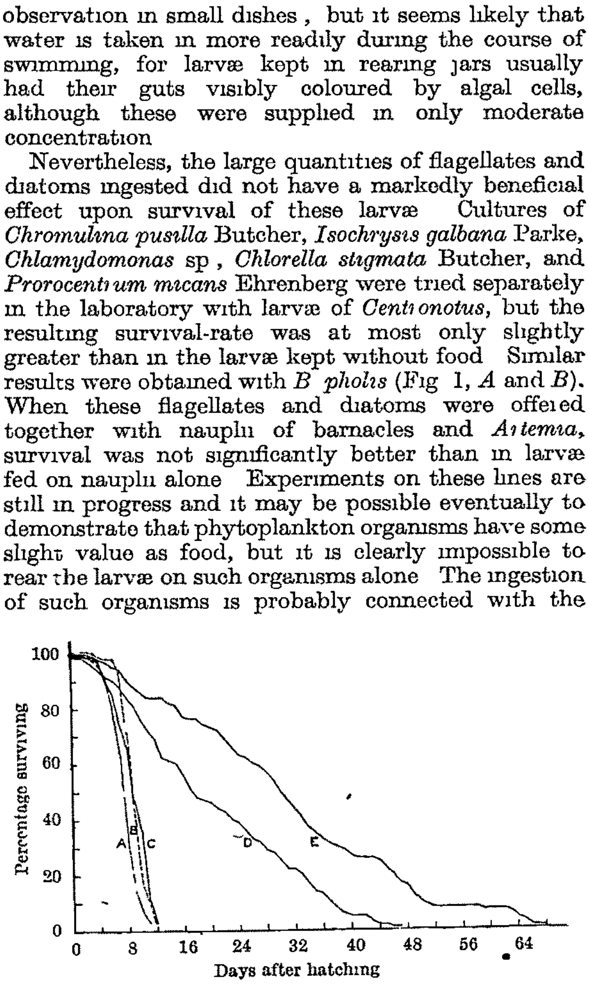

Fig 1 *A*, without food continuous light , *B*, with flagellates, continuous light , *C*, with *Artemia* nauplii, continuous darkness , *D*, with *Artemia* nauplii, continuous light , *E*, with *Artemia* nauplii, alternate light and darkness

drinking of water for osmo-regulation, as demonstrated by Homer Smith[5] in marine teleosts.

Feeding on nauplii, on the other hand, involves deliberate efforts of catching by the larvæ, and they were seen doing this only in the light. Larvæ examined after they had been kept in continuous darkness always had empty stomachs, though they had been supplied with abundant nauplii. Their survival-rate was no more than that of larvæ kept without food (Fig. 1, *A* and *C*). When the only source of illumination was a dim red light, the larvæ of *B. pholis* did not feed but became inactive, and generally remained suspended in the water. Close examination, combined with experiments involving changes of pressure, revealed the presence of a swim bladder with a hydrostatic function, which is absent in adults of this species[6]. The inactivity of the larvæ, which is presumably shown every night, recalled previous accounts of sleeping in fishes[7].

The question of whether such sleep is beneficial was then investigated. Five jars with almost equal numbers of larvæ of *B. pholis* were given 7–8 hr. of illumination during the day and kept in darkness during the night. The same number of jars were kept under continuous illumination. Abundant *Artemia* nauplii were supplied as food to all the jars, particular care being taken to ensure that the larvæ kept under continuous illumination always had plenty of nauplii available as food. Other environmental conditions were equal, and the larvæ were of similar parentage; yet after a few days it was clear that those kept under alternate light and darkness were surviving much better than those under continuous illumination (Fig. 1, *D* and *E*). The rates of survival showed only slight deviations from the mean in all five jars of each batch. After a period of inactivity in the dark, larvæ exposed to light become particularly active, showing more vigorous feeding on nauplii than those kept illuminated all the time.

Population Regulation in Rabbit Nematodes

COMPARATIVELY little information is available on the factors governing the size of nematode infestations in wild mammals. Elton *et al.*[1] showed that infestations of *Nematospiroides dubius* in field-mice (*Apodemus*) tended to become larger as the host increased in weight, and Evans[2] demonstrated a similar tendency for *Graphidium strigosum* in wild rabbits (*Oryctolagus*), but for *Passalurus ambiguus* he found that, after rabbits reached a weight of 3½ lb., infestations declined with further increase in host-weight. The authors interpreted their results as indicating the effects of increasing age of host. Recent work on the parasites of the wild rabbit (*Oryctolagus cuniculus* L.) in New Zealand gives confirmation of Evans's results for *G. strigosum*, and provides the first adequate picture of population-size in *Trichostrongylus retortaeformis*, a picture which differs markedly from those of the other nematodes mentioned above and forms the subject of the present communication.

The size of worm populations was estimated by a dilution-sampling technique[3]; the presence or absence of infective larvæ in the sample was noted, but all later stages were counted. The paunched weight of the host is used as an indication of age, but as such it is only reliable for rabbits weighing less than 1,000 gm., all such animals being less than 9½ months old[4]. Heavier weight groups contain individuals of varying age; but the proportion of animals more than 9½ months old increases with weight, so that there is an increase in the mean age of the sample in each successive weight-group.

Fig. 1 shows the frequency of occurrence of infestations of different size of *T. retortaeformis* in relation to the paunched weight of the host. The results were obtained from the examination of 1,055 rabbits collected over a period of 13 months (March 1950–March 1951 inclusive) in the Tikokino district of Hawke's Bay Province (North Island of New Zealand). The figures for size of infestation represent one-tenth of the total population (the proportion actually counted), and have been grouped on a logarithmic scale because the range of variation is rather wide.

The most striking feature is the very great range in the size of infestations, and this is evident in every

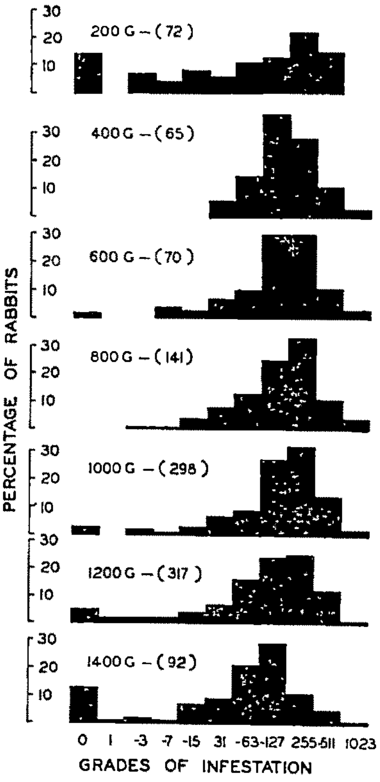

Fig. 1. Frequency of occurrence of different-sized infestations of *T. retortaeformis* in relation to host weight. Figures for size of infestation are grouped on a logarithmic scale. The figures in brackets refer to the number of rabbits in each 200-gm. weight-group, starting from a paunched weight of 200 gm.

weight-group except the second one (400–599 gm), which is based on a slightly smaller sample than the others Heavy infestations were found in some rabbits in every weight class, the largest number of worms counted in one rabbit (paunched weight 1,156 gm) being 937, which indicates a total population of some nine or ten thousand worms The proportion of heavy infestations rises abruptly from the first to the second weight-group, due presumably to the greater chance of acquiring worms as the young rabbits change their diet from milk to grass After this point there is little further increase but, on the contrary, a tendency for light infestations to reappear These facts suggest that heavy infestations are acquired quite early in the life of the rabbit and that there is some mechanism preventing the animal acquiring progressively heavier infestations as it grows older A second point of interest in Fig 1 is that light infestations become increasingly frequent in the heavier rabbits until, in the 1,400 gm weight-class, 12 per cent of the animals had no worms other than infective larvæ

The data presented are probably adequate to give a true picture of *T. retortaeformis* infestations in Hawke's Bay rabbits during 1950–51, but there is evidence suggesting that in some circumstances much higher infestations may occur For example, among 74 rabbits collected at the Auckland Islands (200 miles south of New Zealand) in March 1954, seven had populations exceeding any recorded in Hawke's Bay The largest number of worms counted in one rabbit was 1,920, which is double the highest Hawke's Bay figure The tendency towards a higher proportion of light infestations among the heavier rabbits was even more marked in the Auckland Islands than in Hawke's Bay.

The 'self-cure' mechanism described by Michel[5] for *T retortaeformis* in laboratory rabbits provides a satisfactory explanation for the fact that in most of the classes (Fig. 1) some rabbits contain no worms other than infective larvæ The alternative explanation that the wide range in the size of infestations is matched by an equally wide range in natural resistance among individual rabbits appears less likely, and lacks any experimental support Accepting the 'self-cure' mechanism, and comparing the infestations found in Hawke's Bay with those at Auckland Islands, it is apparent that 'self-cure' may operate at different levels of worm infestation in different rabbit populations This conclusion leads to the suggestion that the abundance of *T retortaeformis* is governed by the resistance of the host, which in turn may be modified by various environmental factors such as the host's food supply[6]. Thus any effect the parasite may have in controlling the numbers of the host is secondary and perhaps additional to that of the environment

Elton *et al* [1] concluded that, since the highest infestations of *N. dubius* occurred in the oldest mice, any increase in the host population by reproduction, and thus a lowering of the average age, causes a reduction in the mean number of parasites per host, thereby reducing the possibility of the parasite acting as a check to the further increase of the host population The present work shows that such a concept would be applicable to *G. strigosum* in rabbits, but not to *T. retortaeformis*, severe infestations of which are common in quite young rabbits

A final conclusion emerging from the present work is that, since abundance of parasites is strongly correlated with age of host (*G strigosum*) and locality of collection (*T retortaeformis*), records of parasite abundance in wild animals are of little significance unless linked with details of age composition and locality of collection of the host sample.

The observations on which this communication is based, together with comparable material on other rabbit parasites, will be published in full elsewhere.

Absorption Spectrum of Deeply Coloured *Cyclo*pentadiene Polymers

*Cyclo*pentadiene can be converted, catalytically by trichloroacetic acid (H*A*), into a brown-red poly-*cyclo*pentadiene trichloroacetic acid ester (I) The colour of this adduct is due to conjugated double bonds[1], which are also responsible for its proton acceptor properties[2], namely, for the fast reversible reaction

$$(\text{I}) + (\text{H}A) \rightleftharpoons (\text{II}), \qquad (1)$$

where (II) is a blue salt-like adduct, formed by transfer of a proton from (H*A*) to (I)

We have developed a technique by which the conversion of *cyclo*pentadiene into (I) or (II) can be carried out at oxygen pressures less than 10^{-3} mm mercury, and by which the light absorption, in the range 2500–30,000 A., could be measured without admitting oxygen to the reaction mixture Absorption bands of (I) of wave-length greater than 3500 A could not be detected, but (II) has a characteristic spectrum in the visible range as shown by curve (*a*) in Fig 1 , this experiment was carried out at a trichloroacetic acid concentration sufficiently high to

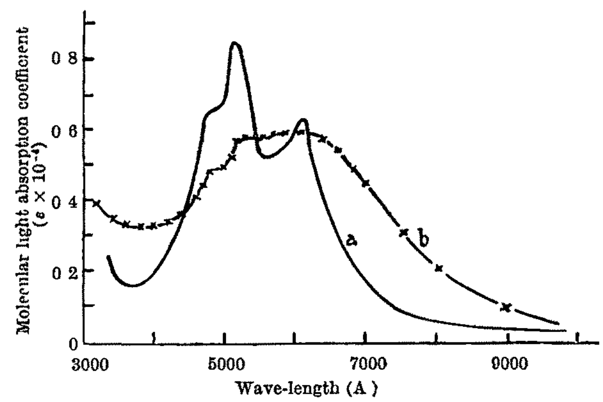

Fig 1. Solvent benzene, temperature 20 0° C , trichloroacetic acid concentration, 1 65 gm mol /l

Curve (*a*), oxygen excluded , measurement carried out 20 hr after start of reaction , polymer concentration, 11 3 × 10^{-4} number average gm mol /l , optical path-length, 0 102 cm

Curve (*b*), ratio of mol oxygen to mol *cyclo*pentadiene at zero time is 1 2 , measurement carried out 24 hr after start of reaction , polymer concentration 6 44 × 10^{-4} number average gm mol /l , optical path-length, 0 205 cm shift the equilibrium of reaction (1) completely to the right-hand side. On addition of oxygen, the spectrum of (II) is fundamentally altered. The various ε-values depend, *inter alia*, on the time of exposure to oxygen and on its partial pressure. The spectrum of oxidized (II), for specified experimental conditions, is shown by curve (*b*). The molar light absorption coefficient, ε, is defined by optical density/optical path-length × *c*, where *c*, the polymer concentration, is calculated from the initial concentration of *cyclo*pentadiene and the number average degree of polymerization specified before[1].

Spectrophotometric tests, in the range 4500–6500 A., were carried out continuously during the conversion of the monomer and it was possible, therefore, to study by an optical method the gradual building up of this coloured polymer. The results of these experiments will be discussed elsewhere.

Mechanism of Osazone Formation

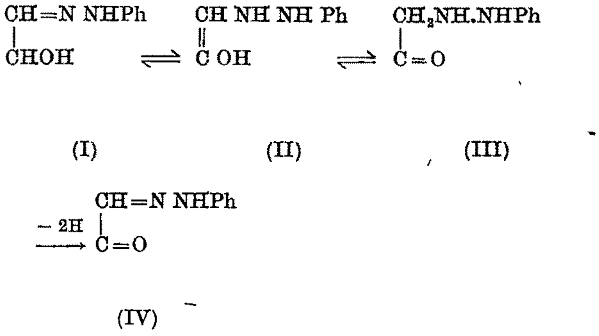
A fact which seems to have escaped attention in formulating a mechanism for osazone formation is that β-alkyl substituted phenylhydrazines are oxidized very readily in air to form phenylhydrazones[1]:

$$R.CH_2\,NH.NH\,Ph \xrightarrow{\text{Air}} R.CH{=}N\,NH\,Ph.$$

Further, it has been found recently[2] that β-acetonyl phenylhydrazine is also oxidized by air at room temperature extremely readily:

$$CH_3.CO.CH_2\,NH\,NH.Ph. \xrightarrow{\text{Air}} CH_3\,CO\,CH{=}N.NH.Ph$$

Here, it seems, is an important clue for detecting the mechanism of osazone formation, since if, as Weygand suggested[3], an Amadori rearrangement (I → III) is assumed



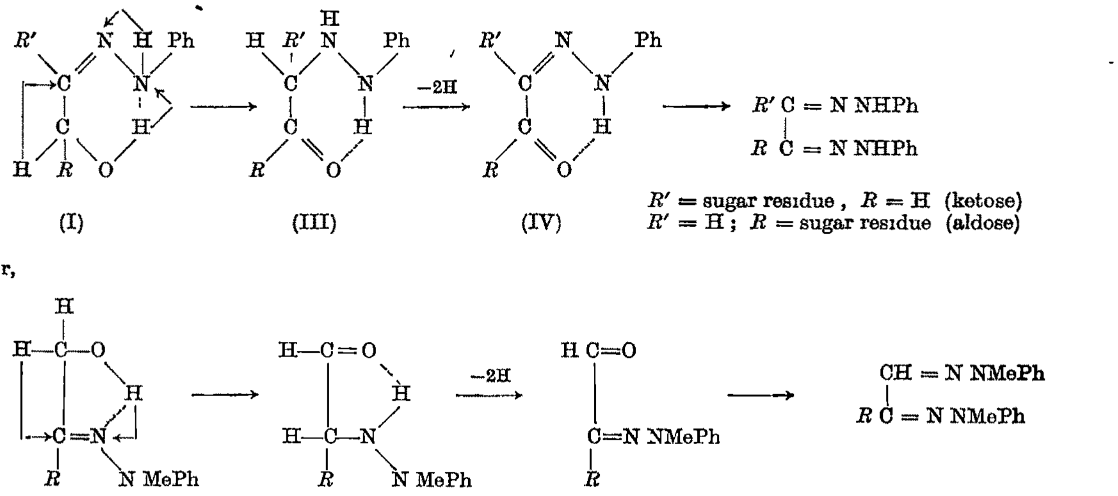
$$\begin{array}{l}CH{=}N\,NHPh\\ |\\ CHOH\end{array} \rightleftharpoons \begin{array}{l}CH\,NH\,NH\,Ph\\ \|\\ C\,OH\end{array} \rightleftharpoons \begin{array}{l}CH_2NH.NHPh\\ |\\ C{=}O\end{array} \xrightarrow{-2H} \begin{array}{l}CH{=}N\,NHPh\\ |\\ C{=}O\end{array}$$

(I) (II) (III) (IV)

then it is no longer necessary to search for an oxidizing agent to convert (III) into (IV). All that is required is a hydrogen acceptor such as oxygen, or the phenyl hydrazonium cation[4], which is reductively cleaved to aniline and ammonia.

This mechanism will accommodate all the known facts on osazone formation, including the observation of Orning and Stempel[5] that the reaction is inhibited at 30° C. in the absence of air. Since oxygen and the phenylhydrazonium cation are competing hydrogen acceptors, one would expect to find a correlation between the yield of aniline (and ammonia) and the quantity of oxygen present.

The formation of osazones and methylphenylosazones may proceed through the hydrogen bonded structures shown below.



R′ = sugar residue, R = H (ketose)
R′ = H; R = sugar residue (aldose)

Two suggestions have been put forward[6] to explain why the reaction is not continued to C_3 of the sugar residue, but a choice between these must await further experimental evidence.

Society for Visiting Scientists (at 5 Old Burlington Street, London, W 1), at 7 30 p m —Discussion meeting—"Colour from the Viewpoint of the Painter and the Scientist" Chairman Prof T A Stephenson, F R S ; Speakers Mr G J R Frankl and Prof W D Wright

Wednesday, February 2

Geological Society of London (joint meeting with the Royal Astronomical Society, at Burlington House, Piccadilly, London, W 1), at 5 p m —Discussion on "The Origin of the Earth" Chairman Prof W B R King, F R S Speakers Prof L Hawkes, F R S , Mr T Gold, Prof C E Tilley, F R S , and Sir Edward Bullard, F R S

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S W 1), at 5 30 p m —Continued Discussion on "The Beaver Report of the Committee on Air Pollution"

Society for Analytical Chemistry (in the Lecture Theatre of the Royal Institution, 21 Albemarle Street, London, W 1), at 6 p m — Prof G Schwarzenbach (Zurich University) "The Complexones and their Analytical Application"

University of London (at the Institute of Laryngology and Otology, Royal National Throat, Nose and Ear Hospital, Gray's Inn Road, London, W C 1), at 6 p m —Prof M Arslan (Padua) "The Effects of Ultra Sonic Waves on the Ear" *

Institution of Electrical Engineers, London Students' Section (at Savoy Place, London, W C 2), at 6 30 p m —Mr J Eccles "The Generation of Electricity in Britain"

Royal Institute of Chemistry (joint meeting with the South-West Essex Technical College Chemical Society, at the South-West Essex Technical College, Walthamstow, London, E 17), at 7 p m —Mr L C Nickolls "Some Chemical Aspects of Forensic Science"

Thursday, February 3

Royal Society (at Burlington House, Piccadilly, London, W 1), at 4 30 p m —Mr H M Rosenberg "The Thermal Conductivity of Metals at Low Temperatures" , Mr R W Ditchburn "Absorption Coefficients in the Vacuum Ultra-Violet Part 3—Methane"

Linnean Society of London (at Burlington House, Piccadilly, London, W 1), at 5 p m —Dr J W S Pringle, F R S "The Evolution of Song in Cicadas"

University of London (at the Institute of Psychiatry, Maudsley Hospital, London, S E 21), at 5 p m —Prof H J Eysenck "Psychology and the Foundations of Psychiatry" *

Physical Society, Acoustics Group (in the Physics Department, Imperial College, Imperial Institute Road, London, S W 7), at 5 30 p m —Prof O K Mawardi "On Heat Maintained Oscillations".

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W C 1), at 5 30 p m —Prof P B Medawar, F R S "Tissue Transplantation Immunity" (From a series of lectures on "The Scientific Basis of Medicine")*

Institute of Metals, London Local Section (at 4 Grosvenor Gardens, London, S W 1), at 6 30 p m —Dr W E Hoare "Tin and Tinplate"

Chemical Society (at Burlington House, Piccadilly, London, W 1), at 7 30 p m —Scientific Papers

Friday, February 4

Society of Chemical Industry (joint meeting of the Manchester Section and the Food Group, in the Engineers' Club, Albert Square, Manchester 2), at 6 30 p m —Meeting on "Some Aspects of Air Conditioning in the Bakery and Textile Industries"

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W C 1), at 6 30 p m — Dr J A Scott "Health" (From a series of University Extension lectures on "Aspects of Social Policy")

British Glaciological Society (at the School of Geography, Mansfield Road, Oxford), at 8 15 p m —Mr G T Warwick "Ice and Caves"

University of London (at Royal Holloway College, Englefield Green, Surrey), at 8 15 p m —Brigadier Sir John Hunt "The British Mount Everest Expedition 1953"

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Prof V B Wigglesworth, F R S "The Control of Metamorphosis in an Insect"

Saturday, February 5

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Prof C von Fürer-Haimendorf 'The Sherpas of the Nepal Himalaya" *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Senior Lecturer (with a degree in agriculture or equivalent qualification and sound experience in practical farming, and, if possible in teaching) in Agriculture at the Cumberland and Westmorland Farm School, Newton Rigg, near Penrith—The Director of Education, 5 Portland Square, Carlisle (February 3)

Head (graduate (preferably science) and with administrative experience) of the Department of Science and General Education—The Principal, London School of Printing and Graphic Arts, Back Hill, London, E C 1 (February 4)

Technician (skilled machinist and/or instrument maker, and preferably with some experience of servicing X-ray therapy equipment) in the Physics Department Workshop—The Secretary and House Governor, Mount Vernon Hospital, Northwood, Middlesex (February 4)

Senior Scientific Officer (with a university degree of high standard in electrical engineering or physics, with mathematics or mathematical physics to final honours standard or equivalent qualifications, and several years experience of research in the above or an allied field) in the Department of Supply, Aeronautical Research Laboratories, Fishermen's Bend, Victoria, Australia, to be responsible for the investigation of instrumentation schemes in the field of aeronautical research, and detailed investigation of resultant problems and the subsequent development of necessary apparatus—The Senior Representative (AP 24), Department of Supply, Australia House, Strand, London, W C 2 (February 5)

Botanist (preferably with experience in microscopy) for work connected with the effect of field factors on fruit characters, especially those affecting the storage life of apples—The Secretary, East Malling Research Station, near Maidstone, Kent (February 7)

Assistant Advisors (with an honours degree in anthropology and administrative experience) on Aborigines in the Federation of Malaya —The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S W 1, quoting BCD 167/60/02 (February 8)

Senior Lecturer (with good qualifications and recent teaching experience, in either physics or chemistry) in Science—The Secretary, Homerton College, Cambridge (February 10)

Senior Lecturer, Grade 1 or 2 (with a good honours degree) in Physics, at the Nigerian College of Arts Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W C 1 (February 14)

Scientists (with a first- or second-class honours degree in physics, engineering, mathematics or statistics, and experience in field, laboratory, or operational research, and preferably with experience in the writing of research reports) in the Field Investigation Group —The National Coal Board, Establishments (Personnel), Hobart House, London, S W 1, quoting TT/914 (February 15)

Lecturer in Animal Production at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W C 1 (February 17)

Chief Lecturer or Senior Lecturer in Veterinary Clinical Medicine, and a Senior Lecturer or Lecturer (Grade 1) in Veterinary Clinical Medicine, at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (Australia, February 19)

University Demonstrator in Physics—Dr F B Kipping, Chemical Laboratory, Pembroke Street, Cambridge (February 19)

Headmaster (graduate of a British university and with sound experience of agricultural education) of the Brymore Secondary Technical School of Agriculture, Cannington, near Bridgwater, Somerset—Chief Education Officer, County Education Office, Trull Road, Taunton, Somerset (February 21)

Lecturer in Plant Pathology , a Lecturer/Senior Lecturer in Bacteriology , a Lecturer/Senior Lecturer in Psychology , and a Senior Lecturer in Education, at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (Australia, February 26)

Reader or Senior Lecturer (with special qualifications in chemical pathology) in Chemical Pathology—The Registrar, The University, Manchester 13 (February 26)

Systematic Botanist (preferably with research interests in quantitative and experimental taxonomy), at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (Australia, February 26)

Head (with high qualifications in geology and experience in both teaching and research) of the Department of Geology—The Principal, Chelsea Polytechnic, Manresa Road, London, S W 3 (February 28)

Lecturer in the Department of Logic and Metaphysics — The Secretary, The University, Edinburgh (February 28)

Lecturer (with an honours degree in physiology, and with experience in teaching experimental physiology to honours students) in the Department of Physiology—The Secretary, Bedford College (University of London), Regent's Park, London, N W 1 (February 28)

Senior Lecturer in Physical Chemistry at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1 (New Zealand, March 1)

I C I Research Fellows (2) in Physics, Chemistry, Pharmacology, Metallurgy, Engineering, Geology or Agricultural Science, or an allied subject—The Registrar, University of Wales, University Registry, Cathays Park, Cardiff (March 31)

Plant and Animal Quarantine Officer (with a university degree with good scientific qualifications and mature experience in the field of plant or animal pests or diseases and their control and prevention, including quarantine measures), with the South Pacific Commission at Noumea, New Caledonia, to carry out investigations, etc , relating to the control of plant and animal pests, diseases, and weeds in the South Pacific, including supervision of a rhinoceros beetle research programme, operation of an information centre and reporting service, and improvement of control and protective measures—The Secretary-General, South Pacific Commission, Noumea, New Caledonia (March 31)

Lecturer (with an honours degree in botany or agricultural botany, and preferably with postgraduate experience in plant physiology, ecology, genetics or virus pathology) in the Department of Agricultural Botany—The Registrar, The University, Reading (April 15)

Turner and Newall Research Fellows in Engineering, Inorganic Chemistry, Physics, and allied subjects—The Registrar, The University, Manchester (April 30)

Agronomist Scientific Officer or Senior Scientific Officer grade (with at least a second-class honours degree with not less than two years appropriate postgraduate experience, preferably including acquaintance with tropical tree crops and up-to-date knowledge of the statistical analysis of field experimental results), at the West African Cocoa Research Institute, to assist in laying down field experiments on various methods of cultivating cocoa—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S W 1, quoting BCD 197/200/05

Assistant or Associate Professor of Statistics, and a Sessional Lecturer in Mathematics—The Dean, Faculty of Arts and Science, University of Alberta, Edmonton, Alberta, Canada

Chemist or Biochemist (with a good honours degree) in the Technical Division for administrative work which is concerned with the assessment and development of inventions in chemical and biochemical fields—The Secretary, National Research Development Corporation, 1 Tilney Street, London, W 1

Chemist (with two or three years experience in research or industry) for physical and chemical research relating to textile industrial operation—The Personnel Officer, Ontario Research Foundation, 43 Queen's Park, Toronto 5, Ontario, Canada

Deputy Director (with high academic qualifications, wide experience in engineering research, and preferably some administrative ability and a knowledge of the motor industry) of the Motor Industry Research Association—The Director, Motor Industry Research Association, Lindley, near Nuneaton, Warwickshire

Laboratory Steward (with recognized qualifications and with a special interest in physics)—The Registrar, Hatfield Technical College, Roe Green, Hatfield, Herts

Lecturer in Education—The Principal, The Training College, Bingley, Yorks

Physical Chemist (with a good honours degree and some research experience (not necessarily in textiles)), to carry out research on dye absorption by textile materials—The Appointments Officer, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester

Physicists, Chemists, Chemical Engineers and Mechanical Engineers—National Coal Board, Central Research Establishment, Stoke Orchard, near Cheltenham, quoting TT/913

Reader in Physics, and Senior Lecturers or Lecturers (3) in Physics—The Dean, College of Arts and Science, Baghdad, Iraq

Research Assistant to design and construct research electronic equipment and assist in its use—The Director, Chemistry Department, The University, Birmingham 15

Scientific Officers (with a first- or second-class honours degree or equivalent in mathematics, physics or economics), in or near London for operational research under the direction of the Scientific Adviser to the Air Ministry—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1, quoting A 384/54A

LECTURES AND COURSES

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

POSTGRADUATE ACADEMIC DIPLOMA IN BACTERIOLOGY

The course for the Postgraduate Diploma in Bacteriology for the Session 1955-56, will commence in October, 1955 This is a full-time day course extending over one academic year The course may be taken by (a) Graduates in Medicine or Veterinary Science desiring to study bacteriology as applied to medicine and hygiene (b) Graduates in science with a first- or second-class honours degree in chemistry, or its equivalent For such students the course covers the fields of general bacteriology, chemical microbiology and industrial microbiology Applications for admission to the Diploma course must be received not later than March 31, 1955

Further information and application forms can be obtained from the Registrar, London School of Hygiene and Tropical Medicine Keppel Street London, W C 1

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF ELECTRONICS

The Department of Electronics gives an advanced course at honours degree standard in electronics The course is full-time for one academic year and the university grants a diploma by examination to students who successfully complete the course Entry qualification is a university degree in physics or electrical engineering, or its equivalent

The next course will commence in October, 1955, and applications for admission should be made now to the Academic Registrar, from whom further details may be obtained

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

(TECHNICAL OPTICS SECTION)

A course of eight lectures and an accompanying practical course on Thin Film Optics, by Dr W Weinstein will be given on Tuesdays and Thursdays at 4 30 p m, commencing Tuesday, February 22, 1955 Fee for eight lectures, 2 gns, and for practical course 4 gns

For further details apply to the Registry, Imperial College, Prince Consort Road, S W 7

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 *to* 64 *inclusive, or a woman aged* 18 *to* 59 *inclusive unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order,* 1952

TECHNICIANS FOR NEW ZEALAND DEPARTMENT OF AGRICULTURE

Applications are invited from technicians with experience and recognized qualifications in (a) bacteriology and pathology, (b) chemistry (c) parasitology, for appointment to the Ruakura (Hamilton) and Wallaceville (Wellington) Laboratories of the Animal Research Division and the Rukuhia (Hamilton) Laboratory of the Extension Division of the Department of Agriculture Salary on appointment for applicants with general certificate of education (or equivalent) and six years' experience from £N Z 555 to £N Z 750 according to experience and qualifications An appointing officer from New Zealand will interview suitable applicants in London

Application forms and general information on conditions of employment may be obtained on request from High Commissioner for New Zealand, 415 Strand London, W C 2 quoting reference No 3/4/40, and mentioning this paper Completed applications to be lodged not later than February 26, 1955

EXPERIMENTAL OFFICER REQUIRED BY Ministry of Supply at Royal Aircraft Establishment Farnborough, Hants in a group doing research on metal extraction processes Knowledge of physical chemistry required and metallurgical experience an advantage Qualifications, higher school certificate (science) or equivalent Salary within Experimental Officer range (minimum age 26), £715 to £880 Women somewhat less —Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K) Almack House, 26 King Street, London, S W 1, quoting F 19/5A

MANCHESTER MUNICIPAL COLLEGE OF TECHNOLOGY

(FACULTY OF TECHNOLOGY IN THE UNIVERSITY OF MANCHESTER)

APPOINTMENT OF LECTURER OR SENIOR LECTURER IN THE DEPARTMENT OF APPLIED PHYSICS

The Governing Body invites applications for an appointment as Lecturer or Senior Lecturer in the Department of Applied Physics, with similar title and status in the university The exact status of the successful candidate will be determined by his qualifications, experience and age Candidates should be graduates in physics who have had extensive research experience of solid state physics and preferably of semi-conductors The successful applicant will be expected to devote himself mainly to research and the supervision of research He will be free from administrative responsibilities but will be required to undertake a certain amount of lecturing Under the general supervision of the Professor of Physics he will be required to build up a new section in the Physics Department Hitherto the Department has concentrated most of its efforts in X-ray crystallography, and it is very well equipped for work in this field The new section is to be housed in part of the extension of the College, which will not be finished until next September, nevertheless it would be convenient if the successful candidate could take up his appointment before then so that he could superintend the equipment of his laboratory Salary scale, Lecturer, £650 to £1 350, Senior Lecturer, £1,400 to £1 750, by annual increments of £50 The appointment may be made anywhere within these scales depending on the qualifications and experience of the applicant Superannuation under the F S S U and family allowances

Conditions of appointment and form of application may be obtained from the Registrar, College of Technology, Manchester, 1 The last day for receipt of applications is March 19, 1955

B V BOWDEN,
Principal of the College

AUSTRALIAN NATIONAL UNIVERSITY

JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

Applications are invited from organic chemists for the position of Research Fellow who will be a research assistant to the Professor of Medical Chemistry Candidates should have a Ph D degree (or equivalent research experience) The successful applicant will undertake full-time research, in laboratories which are well-equipped for the purpose, on the synthesis of new heterocyclic compounds, in particular pteridines, pyrimidines and purines The appointment will be for one, two or three years in the first instance, and if the appointment is made for a period longer than one year, the successful applicant will later be required to transfer to Canberra with the Department The Department's laboratories are at present located at 183 Euston Road, London, N W 1 The salary range is £1,100 to £1,650, and superannuation will be provided on the F S S U pattern

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth 5 Gordon Square London W C 1 with whom applications close on February 28 1955

UNIVERSITY OF MANCHESTER

I C I FELLOWSHIPS

Applications are invited for the above Research Fellowships, founded by Imperial Chemical Industries Ltd tenable in the University and available for research in chemistry physics and allied subjects—e g, pharmacology, engineering, metallurgy The value of the Fellowships will be within the range of £600 to £900 per annum, according to qualifications and experience

Regulations governing the award of the Fellowships may be obtained from the Registrar the University, Manchester, 13, to whom applications should be sent not later than April 30 1955

THE MEDICAL COLLEGE OF ST BARtholomew's Hospital, West Smithfield, E C 1 Applications are invited for the post of Research Assistant to undertake research on the Physiology of Ageing The appointment to commence as soon as possible Applicants should possess a high honours degree in physiology The salary is on a scale of £700 to £1,000 per annum, the commencing point on the scale depending upon qualifications and experience —Applications which should be received not later than February 7 1955 should be addressed to the Professor of Physiology St Bartholomew's Hospital Medical College Charterhouse Square, E C 1

EAST MALLING RESEARCH STATION

Chemist required for mineral analysis of plants The work entails participation in routine analysis and supervision of assistants Applicants for the post, which may be in the Assistant Experimental Officer or Experimental Officer grade, according to age and experience, should have a higher national certificate in chemistry or equivalent qualification Good experience of modern methods of analysis essential Superannuation under the Ministry of Agriculture scheme

Further particulars and application form may be obtained from the Secretary, East Malling Research Station, near Maidstone, Kent, by whom applications should be received not later than March 5, 1955

EXETER COLLEGE

UNIVERSITY OF OXFORD

The Governing Body of Exeter College proposes to elect in the course of Trinity Term, 1955, to a Staines Medical Research Fellowship to be held from October 1, 1955 The fellowship is offered for research in Oxford in one of the medical sciences, such as anatomy, biochemistry, clinical science pathology, pharmacology, physiology It is tenable for a maximum period of five years and is not renewable The annual stipend will be £500, together with various allowances A candidate for the fellowship must not have exceeded 35 years of age, must be of British birth, and should preferably hold a registrable medical qualification

For further particulars apply to the Rector Exeter College, Oxford

UNIVERSITY OF LEEDS

DEPARTMENT OF PHARMACOLOGY

Applications are invited from medically qualified or non-medically qualified candidates for appointment as Demonstrator in Pharmacology, the salary scales are at present under review but it is expected that they will be such as to enable an appointment to be made for a medically qualified candidate within the range £700 to £900 and for a non-medically qualified candidate within the range £550 to £650 a year

Applications (three copies) stating date of birth qualifications and experience, together with the names of three referees, should reach the Registrar, The University, Leeds, 2 (from whom further particulars may be obtained), not later than February 26, 1955

CENTRAL RESEARCH ESTABLISHMENT, National Coal Board (at Isleworth, Middlesex) invite applications for the superannuable appointment of a Metallurgist to carry out research on metallurgical problems arising in mining operations Current work includes a study of hard metal tool materials and an examination of the problems of the incendivity of light alloys Good honours degree in metallurgy or equivalent professional qualifications, good knowledge of physical metallurgy and of technology of engineering and constructional materials, including light alloys and/or special steels, are required Appointment will be according to qualifications and experience as either Scientist II (scale £800 by £35 to £1 150 male), or Scientist III (scale £500 by £25 to £950 male) London location allowance of £34 minimum rising to £82 maximum is payable in addition —Write, giving full particulars (in chronological order) of age, education qualifications and experience (with dates), to National Coal Board Establishments (Personnel) Hobart House, Grosvenor Place London, S W 1, marking envelope T T /918 Original testimonials should not be forwarded Closing date February 19 1955

MINISTRY OF AGRICULTURE AND FISHeries Chief Technical Officer The Civil Service Commissioners invite applications from men for this pensionable post in London in the Fertilizers Seeds and Hill Farming Division Age at least 35 on November 1, 1954 Candidates must have a degree in agriculture or a related subject, but candidates with outstanding experience in this field may be admitted without this qualification Experience in organization and staff control and a knowledge of the agricultural lime trade and the technique of the production of lime and ground limestone are essential Knowledge of the fertilizers and seeds trades would be an advantage Inclusive remuneration (including extra duty allowance where payable), £1 420 to £1 558 Starting pay above minimum for exceptionally well-qualified candidate —Particulars and application form from Secretary Civil Service Commission 6 Burlington Gardens London W 1, quoting No 4421/55 Completed application forms to be returned by February 25, 1955

LOTHIANS RIVER PURIFICATION BOARD

Applications are invited for the post of River Inspector for the area of the Board Salary is £1,000 by £50 to £1,250 and the statutory qualifications are corporate membership of the Royal Institute of Chemistry and of the Institute of Sewage Purification Candidates with other appropriate qualifications may be considered The superannuation scheme involves medical examination

Applications, giving age, qualifications, appointments held (with dates and salaries), along with testimonials should reach the Clerk Lothians River Purification Board, City Chambers, High Street, Edinburgh, 1, not later than February 28, 1955

J STORRAR,
Clerk of the Board

THE UNITED KINGDOM ATOMIC Energy Authority, Aldermaston, Berks, requires a Chemical Engineer in the grade of a Senior Experimental Officer or Experimental Officer for development and design work on new chemical plants Minimum qualifications are Inter B Sc or higher national certificate in chemistry, chemical engineering or mechanical engineering, but chemical engineering qualifications to degree standard would be preferred Applicants for a Senior Experimental Officer post should have had several years' appropriate experience and be able to make design calculations with also a good knowledge of constructional materials and of engineering detail The salary ranges are Senior Experimental Officer (minimum age normally 35), £1,017 to £1,197 (male) per annum Experimental Officer (minimum age 26), £715 to £880 (male) per annum The successful applicant will be required to join the Authority's Principal Superannuation Scheme to be introduced shortly, and the salary scales quoted will be enhanced to cover contributions Housing will be available within a reasonable period for married officers who live outside the Establishment's transport facilities During this period, lodging allowance may be payable to suitably qualified candidates —Application form from Senior Recruitment Officer, A W R E, Aldermaston, Berks Quote ref A 19/WGE /34

NATIONAL COAL BOARD INVITE APPLICATIONS for superannuable appointments as Scientific Technical Officers Grade III at various collieries throughout the country in the Pneumoconiosis Field Research (a long-term investigation into the incidence of pneumoconiosis among mine workers) Salary scale £400 by £20 to £560 male Residence near the colliery required After training the officer will be posted to the colliery where the duties involve shiftwork and spending up to three days a week underground, investigating and measuring environmental conditions, especially dust concentration The remaining time will be occupied in evaluating samples in the laboratory General certificate of education in a scientific subject, or equivalent qualification required Knowledge of mining industry not essential —Write giving full particulars (in chronological order) of age, education, qualifications and experience (with dates), to National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S W 1, marking envelope TT/910 Original testimonials should not be forwarded Closing date February 12, 1955

APPLICATIONS ARE INVITED FOR THE post of Assistant Librarian in the joint library of the Grassland Research Institute and the Commonwealth Bureau of Pastures and Field Crops at Hurley, near Maidenhead Applicants should be qualified librarians with some experience in a scientific library Starting salary according to age up to £487 for men and £467 for women at 25 years or over —Application forms, obtainable from Secretary, Grassland Research Institute, Hurley, Berks, to be submitted by February 7, 1955

APPLICATIONS ARE INVITED FROM women holding degree in biology for appointment of Haematological Technician Previous experience in haematology not necessary In first instance appointment will be made in grade of Technician (£450 to £515 per annum) Promotion to the grade of Senior Technician (£540 to £625 per annum) will be made if satisfactory after probationary period of one year Salary and conditions according to Whitley Council —Apply Dr Mills, Royal Berkshire Hospital, Reading

---

McMASTER UNIVERSITY
DEPARTMENT OF CHEMISTRY
GRADUATE ASSISTANTSHIPS

Applications are invited for part-time teaching and Research Assistantships from persons qualified to register in courses leading to the M Sc and Ph D degrees in chemistry Assistantships normally carry a yearly stipend of $1,400 to $1,600 Assistants are required to devote eight to ten hours per week to duties during the academic session (October to April inclusive) and may devote full time to their research during the summer Research is in progress in the following fields mass spectrometry, nuclear chemistry radiochemistry, natural isotopic abundance ratios and their biological and geological significance, isotope effects, organic reaction mechanisms, physical chemistry of high-polymer solutions, isolation and structure of plant alkaloids, biogenesis of the thyroid hormone intermediary metabolism, inorganic analytical methods

Interested persons should write to Dr R P Graham, Chairman of the Department of Chemistry, Hamilton College, McMaster University, Hamilton, Ontario Canada

---

UNIVERSITY OF LIVERPOOL

Applications are invited for the following Fellowships (i) I C I Research Fellowships in Physics, Chemistry, Engineering Metallurgy and Pharmacology, or any related subject, to which some appointments may be made during the current academic year The appointments will date from October 1, 1955 The salary will depend upon qualifications and experience, but will normally be within the range £600 to £900 per annum, together with F S S U benefits and family allowances (ii) Two Leverhulme Postgraduate Fellowships in the Faculty of Science, tenable for one year at a value of £500, renewable for a second year at a value of £550

Applications, three copies, stating the Fellowship applied for age, details of qualifications and experience, publications, research work in progress and completed, and an outline of the proposed field of research, and, in the case of the Leverhulme Fellowships, whether Nationa Service requirements have been fulfilled, together with the names of two referees, should be received not later than March 1, 1955, by the undersigned, from whom further particulars may be obtained (Candidates overseas who find it more convenient to do so may send one copy only by airmail)

STANLEY DUMBELL,
Registrar

EAST MALLING RESEARCH STATION

A vacancy exists in the Biochemistry Section for research on the biochemistry and metabolism of the fruit tree A good honours degree in chemistry, biochemistry, or botany, a sound knowledge of organic chemistry, and a keen interest in the living plant are required with, if possible, postgraduate experience Salary according to age and experience in the Ministry of Agriculture and Fisheries Scientific Officer Grade Superannuation benefits under the F S S U

Further particulars and application form may be obtained from the Secretary, East Malling Research Station, near Maidstone, Kent, by whom applications should be received not later than March 15 1955

MINISTRY OF SUPPLY, RESEARCH Establishment, S E London, requires Physicist to assist in work involving the application of microscope technique including electron microscopy, to metallurgical and explosive properties This post will probably be transferred from S E London to near Sevenoaks, Kent within next two years Qualifications, higher school certificate (Science) or equivalent, but possession of higher national certificate or degree in physics may be an advantage Previous experience in metallography or in the operation and servicing of electron microscopes desirable Salary within Experimental Officer range (minimum age 26) £750 to £920 (London) Women somewhat less —Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26, King Street, London S W 1, quoting A8/5A

NATIONAL RESEARCH DEVELOPMENT Corporation requires a Chemist (or Biochemist) with good honours degree for an established post in its Technical Division The work is concerned with assessment and development of inventions in the chemical and biochemical fields, is administrative and not experimental, and involves liaison with laboratories throughout the country, including medical schools, and with industry Good salary, superannuation arrangements —Applications stating age, qualifications, experience, present salary, and names of two referees, to The Secretary, N R D C, 1 Tilney Street, London, W 1

NIGERIAN COLLEGE OF ARTS, SCIENCE, AND TECHNOLOGY

Principal C A Hart, T D, D Sc, Ph D, M I C E, F R I C S

Applications are invited from candidates with good honours degrees for appointment as Senior Lecturer (Grade I or II) in Physics Now in the early stages of development, the College is autonomous, complementary in function to University College, Ibadan, and of comparable status It has branches at Zaria, Ibadan and Enugu Salary scales, including overseas pay Grade I £1 665 to £1,850 per annum, Grade II, £1,360 to £1 630 per annum Grading and initial salary according to experience Post is pensionable, but temporary appointment carrying gratuity and slightly higher salary might be made Furnished house provided, rent £109 to £150 per annum according to salary Free first-class passages, once each way for each tour of service for person appointed and wife either passage allowance or maintenance allowance for up to two children under 18 Seven days leave on full salary for each month's resident service Tours of service ten to eighteen months

Write for further information to Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W C 1 Closing date for applications (six copies), February 14, 1955

SOUTH PACIFIC COMMISSION
PLANT AND ANIMAL QUARANTINE OFFICER

Applications are invited for the post of Plant and Animal Quarantine Officer with the South Pacific Commission The successful applicant will be appointed for a period from two to three years, and will be stationed at the Commission's headquarters in Noumea, New Caledonia The Plant and Animal Quarantine Officer is required to carry out investigations, etc, relating to the control of plant and animal pests, diseases, and weeds in the South Pacific, including supervision of a rhinoceros beetle research programme, operation of an information centre and reporting service, and improvement of control and protective measures Applicants should have a university degree with good scientific qualifications and mature experience in the field of plant or animal pests or diseases and their control and prevention, including quarantine measures Fluency in English and French is very desirable Commencing salary will be determined according to qualifications and experience, but will be not less than £Stg 1 600 plus a post allowance of £Stg 540 (single) or £Stg 901 (married)

Further information obtainable from the Secretary-General, South Pacific Commission, Noumea, New Caledonia, to whom applications, supported by a detailed curriculum-vitae, should be sent by March 31, 1955

EMPIRE COTTON GROWING CORPORATION
POSTGRADUATE STUDENTSHIPS, 1955-56

With a view to subsequent appointment to the overseas staff men who have completed their National Service are invited to apply for Studentships in (i) Applied Genetics and Plant Breeding, (ii) Plant Physiology Training will be at a university or institution in the U K, with grants ranging according to location from £25 to £34 10s a month, plus approved fees and other allowances Starting salary in the Corporation's service is not less than £900 per annum, including cost-of-living allowance, with free housing and passages

Details and application forms from the Secretary, Empire Cotton Growing Corporation, 12 Chantrey House, Eccleston Street, London, S W 1

THE FURNITURE DEVELOPMENT COUNCIL a Statutory Body established under the Industrial Organization and Development Act 1947 has two vacancies in the Finishing Section of the Research Department (1) To develop simple test methods for finishing materials, particularly lacquers Applicants should possess a degree in a scientific subject and have had some experience in similar test development work preferably on paints or lacquers The successful applicant will require considerable energy and initiative and the ability to work largely on his own responsibility Travel abroad may be necessary (2) To carry out research of a fundamental character into processes used in the finishing of wooden furniture Applicants should possess a good degree in a scientific subject, preferably physics, and also have research experience not necessarily in the paint or lacquer field Salaries for the above posts will be in accordance with qualifications and experience, but will be generous to the right type of man —Applications to the Director, Furniture Development Council 11 Adelphi Terrace, London W C 2

NATIONAL COAL BOARD
DURHAM DIVISION

Applications are invited for a Scientist Grade II, or Scientific Technical Officer Grade I at No 4 Area Laboratory, Bishop Auckland Durham Salary, Scientist II within scale £800 by £35 to £1 150, Scientific Technical Officer I, within scale £765 by £25 to £915 The successful candidate will be required to take charge of the new Area Laboratory under the direction of the Area Chief Scientist

Applications with full details, to the Area Administrative Officer, Area No 4, National Coal Board Durham Division Howlish Offices Coundon Bishop Auckland, Co Durham by February 5

UNIVERSITY COLLEGE OF THE WEST INDIES

Applications are invited for a Research Fellowship in the Department of Chemistry Candidates should be organic chemists with experience of research preferably on natural products The Fellowship which is of the value of between £750 and £1 100 per annum according to qualifications is for one year but may be renewed Paid return passage to Jamaica

Applications (six copies), detailing qualifications and experience and naming three referees to be received by February 15 by Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square London, W C 1 from whom further particulars may be obtained

OPERATIONAL RESEARCH

British European Airways require a Senior Methods Officer to apply operational research techniques to the study of a variety of managerial and operating problems throughout B E A This is a new and progressive appointment offering wide scope for ability Applicants should have a university degree in science or mathematics with a qualification in statistics, and some years in a position of responsibility, preferably in industry Experience of conducting investigations involving statistical analysis essential Starting salary within the range £1,075 to £1 375 per annum according to qualifications and experience Pension scheme Travel concessions —Details of qualifications and experience to Chief Personnel Officer B E A, Keyline House Ruislip, Middlesex quoting reference B8

MINISTRY OF SUPPLY REQUIRES Chemist or Physicist at Research Establishment near Bridgend Glamorgan, for experimental work on the chemical and physical properties and the measurement of performance characteristics of pyrotechnic systems Qualifications higher school certificate (science) or equivalent, but possession of a higher national certificate or a degree in chemistry or physics may be an advantage Some knowledge of electronic equipment desirable The post may be transferred to Horsham, Sussex within next two years Salary within Experimental Officer range (minimum age 26) £715 to £880 Women somewhat less —Application forms from Ministry of Labour and National Service Technical and Scientific Register (K), Almack House 26 King Street London S W 1 quoting F 18/5A Closing date February 19, 1955

MECHANICAL ENGINEERS REQUIRED at Ministry of Supply Headquarters, London to be responsible to head of section for control progress and co-ordination of development contracts sponsored by Guided Weapons (Engineering) Branch and assist in technical planning of some activities of Branch Qualifications, higher school certificate (science) or equivalent but possession of higher national certificate or degree in mechanical engineering may be an advantage Experience in industry desirable Salary within Experimental Officer range (minimum age 26) £750 to £920 per annum (women somewhat less) —Application forms from Ministry of Labour and National Service Technical and Scientific Register (K) 26 King Street London, S W 1 quoting C 19/5A Closing date February 19 1955

PHYSICIST OR MATHEMATICIAN REquired at Ministry of Supply Headquarters London to investigate data reduction associated with ballistic instrumentation with a view to improving methods of presentation of results and to introducing methods of analysis applicable to automatic computing machines Qualifications, first- or second-class honours degree in physics or mathematics Salary within Scientific Officer range, £492 10s to £885 Women somewhat less F S S U benefits may be available —Application forms from Ministry of Labour and National Service Technical and Scientific Register (K) 26 King Street London, S W 1 quoting A7/5A Closing date February 24, 1955

UNIVERSITY OF CAMBRIDGE
I C I FELLOWSHIPS

Applications are invited for Research Fellowships, value within the range £600 to £900 a year founded by Imperial Chemical Industries Ltd, tenable in the University and available for research in physics chemistry biochemistry engineering metallurgy, pharmacology, chemotherapy or related subjects Applications must be received not later than April 30, 1955

Regulations governing the award of the Fellowships may be obtained from the Secretary-General of the Faculties The Old Schools, Cambridge, to whom all applications should be addressed

COLLEGE OF ARTS AND SCIENCE
BAGHDAD, IRAQ

Applications are invited for the post of Reader and three posts of Senior Lecturer or Lecturer in Physics Term of appointment to commence not later than October 1 1955 Salaries are in the range ID 1 400 to ID 2 400 (1 ID =£1), together with a cost-of-living bonus of at least ID 120 and certain other allowances Passages are paid at beginning and end of contract Annual summer leave is permitted Persons appointed are required to carry on research and to teach candidates for B Sc degree Teaching is in English Climate and conditions are suitable for British families

For further information apply to the undersigned

A A DURI
Dean

UNIVERSITY OF MANCHESTER
TURNER AND NEWALL RESEARCH FELLOWSHIPS

Applications are invited for the above Research Fellowships founded by Messrs Turner and Newall Ltd, tenable in the University and available for research in engineering, inorganic chemistry, physics and allied subjects The value of the Fellowships will be within the range of £600 to £900 per annum according to qualifications and experience

Regulations governing the award of the Fellowships may be obtained from the Registrar, The University Manchester 13 to whom applications should be sent not later than April 30 1955

ENGINEERS AND PHYSICISTS REQUIRED by Ministry of Supply for posts in Instrumentation Section of Royal Aircraft Establishment, Farnborough, Hants (1) Research in techniques and instrumentation for measurement and recording of physical quantities arising from tests in aircraft and missiles An interest in application of physical principles to design of special measuring instruments would be useful (two posts) (2) Research on electronic circuits and equipment for flight test, wind tunnel and allied aeronautical research purposes Qualifications First- or second-class honours degree or equivalent in physics or engineering Some relevant experience may be an advantage Appointments in grade of Scientific Officer within salary range £467 10s to £845 Women somewhat less F S S U benefits may be available —Application forms from Ministry of Labour and National Service Technical and Scientific Register (K) 26 King Street, London S W 1, quoting A13/5A

THE UNIVERSITY OF ALBERTA ANnounces the following vacancies in Mathematics (1) Assistant or Associate Professor of Statistics appointment to be effective September 1 1955 starting salary $5 000 or higher, normal increments $250 (2) Sessional Lecturer in Mathematics for eight months from September 1, 1955 at a gross salary of about $3 600, prospect of permanent appointment —Applications including transcript of academic record curriculum vitae, publications names of two references and recent photograph or snapshot to be sent to Walter H Johns Dean Faculty of Arts and Science, University of Alberta, Edmonton, Canada

RESEARCH ASSISTANT (MAN) WANTED as soon as possible for university work on structure of alloys of high melting point The position offers good opportunities for learning high temperature methods The work is arranged so that the man appointed qualifies as an advanced student for the Oxford D Phil degree Requirements First class honours degree in metallurgy, physics or chemistry Salary according to qualifications Applications from overseas cannot be considered and men with second-class honours should not apply unless they have research experience —Applications to Dr W Hume-Rothery, O B E F R S Inorganic Chemistry Laboratory South Parks Road Oxford

SEVERN RIVER BOARD
POLLUTION PREVENTION DEPARTMENT

Applications invited for appointments in the Board s Laboratories (a) Senior Analytical Chemist Salary in A P T Grade V (£750 to £900) according to qualifications and experience Candidates should hold a degree or equivalent qualification Experience in water, sewage, and trade waste analysis desirable but not essential (b) Junior Analytical Chemist Salary in Grade III (£600 to £725) according to qualifications and experience Candidates should hold a degree or equivalent qualification Appointments are subject to national scheme of conditions of service and to Local Government Superannuation Acts, 1937-1953

Applications, stating age qualifications experience and present appointment with copies of not less than two testimonials, should be sent to the Pollution Prevention Officer at the undermentioned address within fourteen days of the appearance of this advertisement

JOHN V MORLEY,
Clerk of the Board

Portland House, Church Street,
Great Malvern Worcestershire

WEST MIDLANDS GAS BOARD
BIRMINGHAM AND DISTRICT DIVISION
ASSISTANT CHEMIST

Candidates who will be required for duty a one of the works in the Birmingham Divisio must have had some years' experience of th chemical control of a large undertaking an should possess a higher national certificate i chemistry or have reached an equivalent standard The salary will be within Grade 7 (£585 to £66 per annum) of the national salary scales for ga staffs The post is pensionable and the success ful candidate may be required to pass a medica examination

Applications stating age personal details quali fications and particulars of training and experi ence together with the names of two referees should be addressed to Mr J E Wakeford Divisional General Manager West Midlands Ga Board Birmingham and District Division, Ga Offices Edmund Street, Birmingham, 3, to reac him within fifteen days of the appearance of thi advertisement

J C INGRAM
Secretary to the Board

EAST MALLING RESEARCH STATION

Vacancy in the Entomology Section for a mal research worker for studies on Tortricids and lea hoppers associated with tree and bush fruits A really good honours degree, and a keen interes in field entomology are essential research experi ence an advantage Appointment as availabl during 1955 The post will be in the Ministry o Agriculture Scientific Officer grade, carries excel lent research prospects, and is superannuated

Further particulars and application form fron the Secretary, East Malling Research Station nea Maidstone Kent, by whom applications shoul be received not later than April 15 1955

UNIVERSITY OF MANCHESTER

Applications are invited for a full-time post a Reader or Senior Lecturer in Chemical Pathology Candidates need not be medically qualified bu should have special qualifications in chemica pathology Salary scales are (a) for medicall qualified persons Reader £1 800 by £100 t £2 250 Senior Lecturer £1 800 by £100 to £2 000 (b) for non-medically qualified persons Reade £1 250 by £50 to £1 600 Senior Lecturer £1 15 by £50 to £1,500 (salary scales are at presen under review) Initial salary and status accord ing to qualifications and experience Membershi of the F S S U and children s allowance scheme

Applications should be sent not later than Feb ruary 26 1955 to the Registrar, The University Manchester, 13 from whom further particula and forms of application may be obtained

CHESTER BEATTY RESEARCH INSTITUT (Institute of Cancer Research Royal Cance Hospital) Two Technicians required (a) Biochemical technician preferably with experience o manometric techniques or in the isolation o natural products (b) Technician for physical chemistry laboratory for work particularly con cerned with spectroscopic techniques experience in this field would be an advantage Both posts are permanent and superannuable and the salary will be according to age experience and qualifications —Applications marked respectively " Biochemistry " and ' Spectroscopy ' should be addressed to the Chester Beatty Research Institute Fulham Road London S W 3

APPOINTMENTS VACANT

MOTOR INDUSTRY RESEARCH ASSOCIATION

DEPUTY DIRECTOR

Applications are invited for the newly-created st of Deputy Director of the Motor Industry search Association Candidates must have high ademic qualifications, wide experience in engin- ring research and, preferably, some administra- e ability and a knowledge of the motor dustry A salary up to £2,000 per annum will paid to a suitably qualified candidate, and perannuation provided under the F S S U heme

Apply in writing, giving full details of qualifi- tions and experience, to Director, Motor In- stry Research Association, Lindley, near Nun- ton, Warwickshire

DISTILLERS COMPANY LIMITED

The Research and Development Department of the Company have a vacancy for a Mathematician aged 22-26 years for work on a variety of problems concerned largely with instrumentation and physical methods for the study of high polymers Honours degree in mathematics essential, together with some general knowledge of physics, including electronics Salary would depend on qualifications and experience —Apply Staff Manager, The Distillers Co Ltd , 21 St James's Square, London, S W 1 Ref Res 155

WIGGINS TEAPE AND CO, (1919) LTD permakers, require a graduate Chemical En- ieer, age about 35 years preferred, papermaking perience not essential A wood pulp mill in onmouth, S Wales, is being planned for which successful applicant will be required first to ist in the layout, design and building, and n, on completion, to take charge of production Manager —Applicants for this post are asked write in confidence, giving fullest particulars of perience and qualifications, to Chief Personnel icer, Wiggins Teape and Co (1919) Ltd , Ald- e House, Mansell Street, London, E 1

BAYER AGRICULTURE REQUIRE AN EX- ienced Technical Adviser, whose duties will lude liaison with Agricultural Research Insti- es and Colleges and giving advice in the field fungicides, insecticides, and weedkillers nours degree in botany or agriculture and ex- ience in advisory work essential Age 30-40 ary commensurate with qualifications and ex- ience Hotel and travelling expenses reim- sed Staff pension scheme —Write, giving age, ication, experience and salary required, to retary Bayer Agriculture Ltd , Thornycroft use, Smith Square, London, S E 1

RITISH INSULATED CALLENDER'S les Ltd , invite applications for the following ancy at their Leigh Works, near Manchester duate Physicist or Electrical Engineer for the tro-physical Laboratory The work involves study of electrical properties of rubber and hetic insulating materials under a wide range physical conditions Investigational work re- s to the performance of experimental cables odying new and improved designs Candi- s should have an interest in the practical use ll types of electrical measuring equipment but ious industrial experience is not necessary — lications, quoting reference A/26, should be ressed to Staff Officer, B I C C Ltd , Prescot, cs

SSISTANT BIOLOGIST REQUIRED FOR ological work on the deterioration of paper lucts A degree in microbiology or botany chemistry is desirable Salary in range £470 £680 Superannuation (F S S U) Five-day k —Application forms from Printing Packag- and Allied Trades Research Association Ran- s Road, Leatherhead, Surrey (Ref A/BIO 1)

SSISTANT CHEMIST REQUIRED TO in the running of a section devoted to rein- ed plastics Scope for man with initiative practical ability Superannuation scheme — ley Products Ltd , Garman Road, Tottenham, 7

ADY CHEMIST, GRADUATE OR H N C , ired for analysis of electroplating and allied ions —Apply, Electro-Chemical Engineering Ltd , 161 Queens Road Weybridge, Surrey

DISTILLERS COMPANY LIMITED

Applications are invited for the following appointments in the Industrial Group of the Company

SENIOR CHEMIST/CHEMICAL ENGINEER to supervise the operation of the Pilot Plant Division of the Research Department of British Industrial Solvents at Hull The Division includes chemists, chemical engineers several teams of pilot plant operators draughtsmen and a small workshop Age up to 37/38 years A degree in Chemistry or Chemical Engineering is essential, together with a number of years' experience of pilot plant work

ASSISTANT WORKS CHEMIST to undertake control work in the Company's Industrial Alcohol Distillery at Hull Age up to 26 years A degree in Chemistry or equivalent qualification is required, but similar work experience is not essential

ANALYST aged 30-40 years for analytical work in connection with the manufacture of whisky, its by-products and malt extract Duties will include the supervision and training of young chemists in this field A degree in Chemistry or equivalent qualification is necessary and appropriate experience in general analytical and bio-assay work is desirable The post is tenable near Stirling in Scotland

Salaries for the above posts would depend on qualifications and experience Apply Staff Manager, The Distillers Co Ltd , 21 St James's Square, London, S W 1 Ref. DCL/G2

THE PYRETHRUM BOARD OF KENYA require two female Chemists, primarily to assist under Senior Chemists in the analysis of pyrethrum and participation in chemical investigations concerning the industry High degree of accuracy and reliability is required Salary £600 by £20 to £660 then £660 by £25 to £735, plus cost of living allowance, which is at present 10 per cent of the basic salary Post provides for home leave, medical benefit scheme, provident fund, and free air passages Hard furnished flats available Candidates should have had scientific training and experience, preferably possessing a B Sc degree or an intermediate pass, with chemistry as principal subject Candidates without these qualifications, but with a sound scientific grounding will be considered —Write Box JA/112, c/o 95 Bishopsgate, E C 2

RESEARCH SCIENTIST, ENGINEER, OR Mathematician, is required in London by an Operational Research Group in a major industry to study comparative economics of various methods of doing same operation and may be required to lead small team Previous experience of operational research, although desirable, not essential First- or good second-class honours degree in science, engineering or mathematics and some years' experience in research with a good analytical approach and ability to write clear and logical reports is required Salary on appointment depending on qualifications and experience, in scale £858 to £1,232 inclusive —Write, giving full particulars of age, education, qualifications and experience (with dates), quoting this paper, to Box 630, T G Scott and Son, Ltd , 143-147 Regent Street London W 1 Original testimonials should not be forwarded Closing date February 15, 1955

APPLICATIONS ARE INVITED FOR SCIENtific Officers for the British Steel Castings Research Association, Broomgrove Lodge, Sheffield 10 Posts vacant for candidates with either metallurgical or engineering bias to their training Acquaintance with foundry practice a recommendation This Association is building a new experimental station Prospects good for future progress Salary according to qualifications and experience Usual professional qualifications expected

ANALYTICAL CHEMIST REQUIRED BY firm of manufacturing chemists for the control of quality of pharmaceutical products and their raw materials and for the development of analytical processes for the standardization of new products Well equipped laboratory in N W London Commencing salary £750 to £800 Contributory pension scheme —Please address applications which should state age, qualifications experience, etc to Box 633 T G Scott and Son, Ltd 143-147 Regent Street, London, W 1

MULLARD RESEARCH LABORATORIES

invite applications for two types of permanent positions in its Vacuum Physics Laboratory In both cases, the work involves research and development in the realm of semi-conductors, solid state physics and photo devices

(a) SENIOR PHYSICISTS to act as Group Leaders with several years of academic or industrial research experience, preferably, but not necessarily, in the above fields

(b) PHYSICISTS with honours degrees, to work in research and development teams—with or without previous experience

In both cases, the positions offered are progressive and pensionable, and carry attractive salaries Candidates, free of national service obligations, should apply,
quoting reference V P L (J),
to Mr G A Taylor,
Personnel Manager,
Mullard Research Laboratories,
Cross Oak Lane,
Salfords, near Redhill, Surrey

A VACANCY FOR A YOUNG MALE science graduate exists in the laboratories of the Research Association of British Rubber Manufacturers Candidates should possess a pass degree in the physical sciences The person appointed is required to assist in technological investigations in the laboratories and must be prepared to spend time away from the laboratories carrying out investigations in rubber factories The appointment will be initially on the Technical Officer Scale (£475 by £25 to £675), with expectation of promotion to Senior Technical Officer (£600 by £30 to £870) Candidates already having industrial or other experience will be considered appropriately The post would be eminently suitable for someone wishing to familiarize himself with industry and gain experience before taking an executive industrial position —Applications, giving full particulars of age, qualifications and experience, to be sent to the Secretary, RABRM, Shawbury, Shrewsbury, Shropshire

AN ORGANIC CHEMIST IS REQUIRED BY British Schering Manufacturing Laboratories Ltd , Hazel Grove, Cheshire, to take charge of a small Development Laboratory The position would suit a university graduate with two or three years' industrial experience A salary of not less than £700 per annum will be paid, according to qualifications and experience

A PHYSICIST WITH INDUSTRIAL EXPERIence of Instrument development is required to join a small team engaged in the design and manufacture of special-purpose apparatus The work is concerned with a wide variety of physical principles and manufacturing techniques A man possessing a general science degree, preferably including chemistry and with practical experience of mechanical and electrical engineering would be suitable The appointment is at the Applicational Research Centre of a Major Oil Company located near Chester Starting salary according to age, qualifications and experience Attractive pension benefits —Write, giving full details experience, qualifications, age, marital status, to Box ZT 705, Deacon's Advertising, 36 Leadenhall Street, London, E C 3

CHIEF CHEMIST REQUIRED BY FIRM specializing in the rare metals to supervise both routine and research laboratories Ph D or equivalent degree with some industrial experience Commencing salary £1,500 per annum Contributory pension scheme —Box 636, T G Scott and Son, Ltd , 143-147 Regent Street, London, W 1

ASSISTANT REQUIRED FOR RESEARCH work in connection with the marine transport of refrigerated cargoes Knowledge of applied physics is required and the work will involve a certain amount of work at various ports Applicants should have a general degree or equivalent and have completed national service Salary will be according to experience within the range £400 to £600 per annum —Apply in writing to Technical Director, Refrigerated Cargo Research Council, Falcon Yard, Cambridge

ENGINEERS and PHYSICISTS

are required by BRITISH TELECOMMUNICATIONS RESEARCH LTD for work on long term research and development projects in the following fields —

(a) Wide-band line communication systems

(b) Wide-band microwave radio systems, including aerials and propagation

(c) Point-to-point television transmission systems

(d) Measuring and testing equipment for the above

(e) Magnetic materials and semiconductors

Attractive posts are offered to qualified engineers with experience in any of the above fields, and further vacancies exist for junior engineers and technical assistants

The Company operates a superannuation scheme, and offers attractive working conditions with generous holiday and leave arrangements, and good social and recreational facilities

All applications will be dealt with in confidence and should be addressed to the Director of Research, British Telecommunications Research Ltd, Taplow Court, Taplow, Bucks

---

JOSEPH LUCAS, LIMITED, HAVE AN INteresting vacancy in their research and development laboratories which would be suitable for a young graduate with honours degree in mathematics or physics The work is largely of a fundamental nature and is concerned with acoustics and mechanical vibrations Previous industrial experience is not necessary —Please reply, giving qualifications, age, and any other relevant details, to Personnel Manager, Joseph Lucas (Electrical) Ltd, Great King Street, Birmingham, quoting reference PM/D/59

THE B T H COMPANY HAVE A vacancy in their Research Laboratory for a Chemist or Physicist to engage in the preparation and processing of silicon for use as a crystal rectifier at ultra-high frequency —Applicants should possess a degree in physics or in chemistry and should write, giving their age and other particulars to the Director of Research, British Thomson-Houston Co, Ltd, Rugby, quoting Reference ATJ

PROFESSIONALLY QUALIFIED ENgineers and Physicists are required to explore and develop new circuits based on transistors —Applicants should write to the Director of Research, British Thomson-Houston Co, Ltd, Rugby, quoting reference BR and stating their age, qualifications and experience

---

THE B T H COMPANY HAVE vacancies in their research laboratory for Assistants in the production, treatment and processing of silicon in very pure form Applicants should have some chemical knowledge and preferably hold a national certificate in chemistry or physics —They should write, giving their age and other particulars to the Director of Research, British Thomson-Houston Co, Ltd, Rugby, quoting reference ON

ENGINEER AGED 25 /35 WITH ELECTRIcal or physicist degree required by Cable Company in London area for development work on testing equipment for telecommunication cables Permanent and pensionable position at salary commensurate with experience and qualifications —Apply, giving full particulars to Box 617, T G Scott and Son, Ltd, 143-147 Regent Street, London, W 1

SENIOR TECHNICIAN, WITH EXPERIENCE in biochemistry and/or biology required for position of Research Assistant to the Research Manager of a company manufacturing pharmaceutical and medicinal preparations The post is a responsible one, and calls for a first-rate thorough worker, possessing keenness and initiative Contributory pension scheme —Apply to Secretary, Benger's, Limited, Holmes Chapel, Cheshire

---

ENGLISH ELECTRIC CO, LTD, WISH TO extend their present laboratory facilities for study of the effect of environmental conditions on guided weapons and their components Applications are therefore invited from Senior and Junior Engineers to direct and carry out this work A wide variety of electrical, mechanical and physical testing is under consideration, and, although previous experience of guided weapons is desirable, it is by no means essential The possession of an engineering or physics degree, H N C, or similar qualification, coupled with some experience in designing and handling ingenious electrical and mechanical test contrivances, would form a satisfactory qualification Housing assistance can be given if required —Please write, stating age, experience and qualifications, to Dept C P S, 336-7 Strand, W C 2, quoting Ref 1000F

IMPERIAL CHEMICAL INDUSTRIES, DYEstuffs Division, have a vacancy in their laboratories in the Manchester district for a young woman honours graduate who has specialized in biological science, preferably with some experience in microbiology The appointment is concerned with biological control and the manufacture of antibiotics —Applications, giving full particulars of age, qualifications and experience, should be addressed to the Staff Department, Hexagon House, Blackley, Manchester, 9

BRITISH NYLON SPINNERS, LIMITED The Company's expanding activities will give rise to further appointments, during the next few months, covering a wide field of scientific endeavour Graduate Scientists and Textile Technologists, whether available now or later, are invited to register their interest at this stage, and where necessary exploratory interviews will be arranged involving no obligation The openings will cover a range of work including pure research, applied research plant experimentation and the development of new manufacturing techniques up to full scale operation For men with suitable ability and inclinations there will be opportunities for specializing in the new advanced forms of technology arising with the advent of synthetic fibres and their textile applications Several of the appointments will be at a senior level, and the Company will welcome tentative inquiries from chemists, physicists and textile graduates —These will be treated in strict confidence, and should be addressed to the Personnel Manager, British Nylon Spinners, Limited, Pontypool Mon

ENGINEER AGED 22/35 REQUIRED BY Cable Company in London area for testing and maintenance of electronic equipment in new instruments for automatic testing of telecommunication cables —Apply, giving full particulars to Box 618, T G Scott and Son Ltd, 143-147 Regent Street London, W 1

APPLICATIONS ARE INVITED FOR POSTS in a development laboratory located in Northamptonshire Minimum qualification required is a degree in physics or the equivalent Experience in microwave work would be advantageous —Box 628, T G Scott and Son Ltd 143-147 Regent Street, London, W 1

UNICAM INSTRUMENTS, LTD

Applications are invited from electron engineers for positions in the develo ment and inspection departments of Unicam I struments of Cambridge This company is e gaged in the manufacture of important instr ments, combining original optical and electron design, which are much in demand for academ and industrial research and process control t world over Good salaries according to quali cations will be paid —Applicants should send f details of age, education and experience, to t Personnel Manager, Unicam Instruments Lt Arbury Works, Cambridge

---

ENGINEER WANTED BY IMPERIA Chemical Industries Ltd, Alkali Division, Wi nington, Northwich, Cheshire, to do research industrial chemical operations such as heat tran fer and matter transfer Candidates aged 25- should possess an honours degree in engineeri (preferably mechanical) and have received su practical training as is required for Assoc Membership of the major Engineering Institutio Starting salary, according to age and experience Applications, giving details of age and experienc should be addressed to Staff Manager

---

BRITISH NYLON SPINNERS LTD, HAV a vacancy in their Library and Information Se tion for a woman graduate in chemistry S will be mainly concerned with assisting membe of the Research and Development Departme in their work by carrying out searches in scienti literature, and with the selection of informati of interest from new material as it is publishe Previous library experience is not essential T appointment is permanent and pensionable —A ply in writing to Personnel Manager Pontypo Mon

---

A PROFESSIONALLY QUALIFIED Engineer or Physicist is required for the development of electrical spark erosion methods as applied to the cutting of hard metals —Applicants should write to the Director of Research, British Thomson-Houston Co, Ltd, Rugby, quoting reference BL, and stating their age, qualifications and experience

---

INDUSTRIAL ORGANIZATION CO cerned with application of photographic proces and apparatus requires a first-class Senior As tant to undertake comprehensive duties in Patent Department Interests are world-wi An extensive knowledge of patent procedures necessary —Write Box 626, T G Scott and S Ltd, 143-147 Regent Street, London, W 1

GRADUATES WITH HONOURS DEgree are required by the BTH Co, Rugby, for research into the physics of light emission from electric discharges and from incandescent surfaces The work will involve radiation measurement and the experimental development of new light sources —Applicants should write to the Director of Research, British Thomson-Houston Co, Ltd, Rugby, giving their age, qualifications and college, quoting reference RH

HONOURS GRADUATES IN PHYSICS Electrical Engineering are required for advan work in a Quartz Crystal Laboratory The p tions offered afford excellent opportunities young men to specialize in the study of pie electric materials from both the theoretical practical view points An interest in mathema and electronics would be an advantage for work Houses can be made available to succ ful applicants —Apply in writing, to the Person Manager, Standard Telephones and Cables L Crystal Division, Industrial Estate East, Harl Essex

---

QUALIFIED ELECTRICAL ENGINEER Physicist required for work on the design utilization of rubber cables for a wide variety applications, mainly for power distribution in mines, aircraft, ships, etc The position of good opportunities for further advancemen Apply Box 632 T G Scott and Son Ltd, 1 147 Regent Street, London, W 1

GRADUATE CHEMIST METALLURG or Chemical Engineer required to deal with pr lems relating to the installation of electropla plant and process control Applicants must h completed military service and be willing to tra —Apply, Electro-Chemical Engineering Co, L 161 Queens Road Weybridge, Surrey

MULLARD RESEARCH LABORATORIES

nvite applications from Scientists to work n its Vacuum Physics Laboratory The osts provide opportunities for physicists or hysical chemists to carry out original re- earch in the field of surface effects in high acuum

Some of the vacancies are for senior cientists with previous research experience n mass spectrometry, gas-solid sorption roblems, or in some allied field

The work offers considerable individual esponsibility and opportunity for original research, and whenever possible, publication is encouraged

Salaries according to age, experience and qualifications Excellent conditions of employment, including contributory pension scheme Apply, quoting reference V P L (R), to Mr G A Taylor, Personnel Manager, Mullard Research Laboratories, Cross Oak Lane Salfords near Redhill Surrey
